***OLIGOSOMA* SPP.** (New Zealand Skinks). **PREDATION.** On 23 November 1998, I observed an adult European starling, *Sturnus vulgaris*, attempting to feed its young on Stephens Island, a reserve in Cook Strait, New Zealand. While seated in the pasture about 40 m from a shearing shed, I observed a starling flying in circles and landing in a nearby shrub, *Coprosma repens*. The starling's nest was in the roof of the shearing shed, but the bird was reluctant to enter while my colleagues and I were nearby. The repeated attempts by the starling to enter the nest enabled me to identify, with the use of binoculars, that it was carrying a tailless speckled skink, *Oligosoma infrapunctatum*. *O. infrapunctatum* is the largest skink on Stephens Island, reaching a SVL of up to 106 mm (Gill and Whitaker 1996. New Zealand Frogs and Reptiles. Bateman Field Guides, David Bateman Ltd., Auckland, New Zealand. 112 pp.). After repeated aborted efforts to access the nest, the bird ate the skink. Within 20 minutes the bird returned with a large mygalomorph spider, repeating the whole performance. During the next hour, it returned with two skinks, both adult *O. lineoocellatum*. Both skinks had lost their tails. As for these last two prey items, the bird ate the first, and eventually entered the nest with the second.

I know of no other report of starlings eating reptiles in New Zealand. When one bird can capture three large skinks within the period of 1.5 h, the species has the potential to be a major predator of lizards in New Zealand. Interestingly, the starling returned on three consecutive occasions with tailless bodies of skinks. Presumably, the tails were lost during capture, but the bird still captured the skink. Whether the bird had consumed the tails is not known.

The most notable feature of Stephens Island is that it contains the largest and most secure population of tuatara, *Sphenodon punctatus*, in New Zealand. Adult tuatara emerge throughout the day under the cover of forest on Stephens Island, but rarely in the pasture where predation by harriers, *Circus aeruginosus*, is likely (unpubl. observation). Given that starlings may forage in the forest, as well as in the pasture, and given that juvenile tuatara are considerably smaller than the skinks that I observed to be taken, there is a high likelihood that starlings may be an introduced predator of juvenile tuatara also.

PHRYNOSOMA ORBICULARE ORBICULARE (Mexican Plateau Horned Lizard). **REPRODUCTION.** At present, few data exist on reproductive characteristics of *Phrynosoma orbiculare orbiculare* (Fitch 1970. Univ. Kansas Mus. Nat. Hist. 52:1–247). Here we report reproductive data for two female specimens of *P. o. orbiculare*. On 27 May 1996 we collected a juvenile female (XR 0149: 73.1 mm SVL, 35.3 mm tail length, 35.0 g) at Las Comadres (elevation 2240 m; oak forest), municipality of Guadalcázar, San Luis Potosí, México. On 15 March 1997 we

collected a gravid female (XR 0538: 110.5 mm SVL, 53.7 mm tail length, 95.0 g) at San José de las Flores (22°40'46"N, 100°24'52"W; elevation 1890 m; xerophilic brushland). The juvenile female had 22 non-vitellogenic follicles (2.4 mm length, 2.0 mm width). The gravid female had 17 embryos with a mean mass of 1.165 ± 0.039 g (0.773–1.353), length 11.259 ± 0.262 mm (9.7–13.7), width 9.082 ± 0.273 mm (7.0–10.9), and volume 525.51 ± 38.9 mm^3 (300.7–867.9). The relative clutch mass (Vitt and Price 1982. Herpetologica 38:237–255) at the time of collection was 0.255. *Phyrnosoma o. orbiculare* and other closely related species such as *P. douglasi* (Ashton and Ashton 1998. Herpetol. Rev. 29:168–169) are viviparous.

We thank H. M. Smith and H. Hernández for their help and advice during the field work, and M. Espinoza and the local authorities for their logistic help. This study was supported by CONABIO project R045/98 and CONACYT project # 27618-N.

SCELOPORUS OLIVACEUS (Texas Spiny Lizard). **PREDATION.** Clark (1949. J. Tennessee Acad. Sci. 24:244–261) found 78 mammals and 17 birds in stomachs of 100 *Elaphe obsoleta* in Louisiana. Barbour (1950. Copeia 1950:100–107) found that 47% of the prey eaten by *E. obsoleta* were mammalian and 53% were avian. Kennedy (1964. Texas J. Sci. 16:210–215) reported an *Anolis carolinensis* from a juvenile *E. obsoleta*. Here we report predation on *Sceloporus olivaceus* by *E. o. lindheimeri* in Texas.

On 29 October 1998, an *E. o. lindheimeri* was captured crossing a park road in Cedar Hill State Park, Dallas Co., Texas, USA, during a herpetological survey (Permit #51-98). The stomach of the snake was fully distended. During measurement of the snake (55.0 cm SVL; 11.3 cm tail length) it regurgitated a *S. olivaceus*. The lizard was partially digested and was missing the anterior half of its body. The remains of the lizard, measuring 148.4 mm TL, were placed in the University of Texas at Arlington Collection of Vertebrates (UTA R-45193).

We thank Ardell Mitchell for reviewing this note and the staff of the Dallas Zoo Department of Herpetology for their support. We also thank the staff of the Cedar Hill State Park and Texas Parks and Wildlife Department for issuing necessary permits.

Submitted by **RICHARD D. REAMS** and **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, Dallas, Texas 75203, USA, and **JOHN M. DAVIS**, Texas Parks and Wildlife, P.O. Box 941, Cedar Hill, Texas 75106, USA; e-mail (RDR): Hylareams@aol.com.

SCINCELLA LATERALIS (Ground Skink). **HATCHLING MORPHOMETRICS**. On 14 June 1999, two adult female *Scincella lateralis* were collected outside of the Dallas Zoo's Bird and Reptile Building, Dallas, Texas, USA. Female number 1 measured 40.6 mm SV, 5.2 mm tail length, and weighed 0.90 g (post oviposition). Female number 2 measured 43.8 mm SVL, 49.9 mm tail length, and weighed 1.2 g (post oviposition). On 15 June 1999, female number 1 deposited two eggs with a mean length of 9.37 mm (± 0.01), mean diameter of 5.26 mm (± 0.03), and mean weight of 0.14g (SD < 0.01). The next day female number 2 deposited four eggs with a mean length of 8.38 mm (± 0.05), mean diameter of 5.62 mm (± 1.57), and mean weight of 0.16 g (± 0.02). All eggs were placed in a 1:1 vermiculite:water mixture and artificially incubated at 28°C. During incubation one egg, containing a dead embryo, was removed. On 20 July 1999, the remaining five eggs hatched. Mean measurements of hatchling skinks were as follows: SVL of 18.9 mm (± 1.11), tail length of 27.6 mm (± 1.36), and weight of 0.14 g (± 0.01).

Submitted by **RUSTON HARTDEGEN**, Dallas Zoo Department of Herpetology, 650 South R.L. Thornton Freeway (I35-E), Dallas, Texas 75203, USA (e-mail: rustonh@sprintmail.com).

TROPIDURUS NANUZAE (NCN). **ENDOPARASITE.** Helminths are common gut parasites of amphibians and reptiles (Aho 1991. Parasite Communities: Patterns and Processes. Chapman and Hall, New York, 429 pp.). *Tropidurus nanuzae* (Tropiduridae) is an endemic lizard from the Espinhaço mountain chain, southeastern Brazil, occurring at sites above 1000 m. Ecological data for this species are scant. In a population from an area of rupiculous vegetation at Serra do Cipó (19°12'S, 43°30'W), Minas Gerais state, we found nematodes of an undescribed species of the genus *Subulura* Moulin, 1860 (Subuluridae) parasitizing the intestine of *T. nanuzae*. Nematode voucher specimens are deposited at the Coleção Helmintológica of the Instituto Oswaldo Cruz (CHIOC 34196 and 34197). In our sample (N = 55 lizards examined) this nematode's prevalence was 65.5% (36/55) and the mean intensity of infection was 20.2 ± 27.2 nematodes/lizard. The high prevalence suggests that this species is an effective gut parasite of *T. nanuzae*. Nematodes of the genus *Subulura* are common parasites of avian and mammalian hosts but were not known to parasitize reptiles (Vicente et al. 1993. Rev. Bras. Zool. 10[1]:19–168; Vicente et al. 1995. Rev. Bras. Zool. [Supl. 1]:1–273; Vicente et al. 1997. Rev. Bras. Zool. [Supl. 1]:1–452). This is the first record of lizard infection by nematodes of the genus *Subulura*.

Support was provided by CNPq grants to MVS (Nos. 301117/95-0 and 400339/97-8) and to JJV (304600/79-8).

VARANUS PANOPTES (Northern Sand Goanna). **DIET.** *Varanus panoptes* is the largest goanna of tropical northern Australia, attaining a total length of up to 1.5 m (Storr et al. 1983. Lizards of Western Australia II: Dragons and Monitors. W.A. Museum Press, Perth. 113 pp.). Hatchlings are ca. 30 cm in length and weigh ca. 30 g (Bennett 1998. Monitor Lizards: Natural History, Biology and Husbandry. Edition Chimaira, Frankfurt. 352 pp.). Many large monitor lizards (*Varanus* spp.) are described as being insectivorous when young and progressing to a more carnivorous diet upon maturity (Auffenberg 1981. The Behavioral Ecology of the Komodo Monitor. University of Florida Press, Gainesville, Florida. 406 pp; Green et al. 1986. Aust. Wildl. Res. 13:585–595). Documentation of the dietary habits of many varanid hatchlings, however, is sparse.

In January 1998, a hatchling *V. panoptes* was captured in a drain within the grounds of the Northern Territory University, Casuarina Campus. The hatchling was placed in a cloth bag and taken to the laboratory where it was measured and weighed. A scat was deposited in the bag and this was soaked in alcohol and later rinsed, sieved (Sieve Type 1507, Endicotts, London), and dried in an oven (105°C) for seven days.

The lizard's total length was 28.4 cm and it weighed 100 g. One grasshopper, two skink tails, and the remains of a bird were recovered from the scat material. These represented 29%, 28%, and 43% of the dry weight, respectively. This is the first documentation of a carnivorous diet in a hatchling varanid and it may explain the larger than expected mass of this specimen. The prey items were probably opportunistically encountered but it appears that varanid hatchlings will exploit vertebrate prey if available.

SERPENTES

AFRONATRIX ANOSCOPUS (Brown Water Snake). **COLORATION**. Previous authors have noted dorsal pattern variation in *Afronatrix anoscopus*, but this has not been quantified (Cansdale 1970. West African Snakes. Longmans, London. 74 pp.; Rossman 1976. Herpetologica 32:256–257; Villiers 1950. Les Serpents de L'Ouest Africain. Institut Francais d'Afrique Noir, Dakar. 148 pp.).

From June 1984 to July 1987, I collected 12 *A. anoscopus* from the same 30-acre area in the town of Yekepa, Nimba County, Liberia. Two specimens were dead when collected. Of the rest, two died in captivity, seven were returned to the wild (at various locations in the 30-acre area), and one was donated to Steiner Zoo, Monrovia, Liberia. Specimen sizes, color patterns, and scalation data ensured that none of the released specimens was counted twice in this study.

The dorsum of *A. anoscopus* is brown, with or without black markings. Of the 12 specimens collected, markings were absent in two specimens (17%). Markings consisted of two staggered rows of black spots the size of a scale or less, in one specimen (8%). Markings consisted of two staggered rows of black spots the size of three to five scales, in two specimens (17%). Markings consisted of bold, black, transverse bars—some broken at the midline, some continuous—in seven specimens (58%).

Mr. Alfred Yeanay, who farmed rice in Yekepa, found seven of the *A. anoscopus* used in this study. His son, Torseh Yeanay, found one specimen. I thank the Yeanays for their help.

Submitted by **PHIL SENTER**, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA (e-mail: beccafaye@worldnet.att.net).

CHARINA BOTTAE (Rubber Boa). **ANTIPREDATOR BEHAVIOR**. In September 1998, a birdwatcher (name withheld by request) witnessed an immature red-tailed hawk (*Buteo jamaicensis*) feeding on a rubber boa (*Charina bottae*). The hawk was perched in a tree on the southeast shore of Washoe Lake, Washoe Lake State Park, Washoe Co., Nevada, USA (39°15'N, 119°46'W, ca 1650 m elevation). The bird suddenly fell from the tree into the shallow water below, then walked out onto the lakeshore whereupon it dropped dead. Upon inspection, the remains of a partially eaten rubber boa were found in the hawk's mouth and the middle third of the snake was tightly coiled around the bird's neck. Apparently the hawk had captured the rubber boa, and in the process of subduing and consuming the snake, the dying boa managed to place a few coils around the hawk's neck and strangle it. Presumably the snake was already dead when the hawk succumbed because the snake's carcass was both headless and tailless (the remaining body section measuring 16.5 cm). Remnants of down feathers were attached to the snake's body. Although red-tailed hawks are known to eat snakes (Farrand [ed.] 1983. The Audubon Society Master Guide to Birding, Vol. 1. Alfred A. Knopf, New York, New York. 447 pp.), to our knowledge this is the first record of a rubber boa strangling a hawk during a predatory encounter. This is the second recent record of a snake killing a red-tailed hawk during a predatory encounter in which the snake was the intended prey (Vandermast 1999. Herpetol. Rev. 30:169).

R. E. Espinoza confirmed the identity of the snake. The boa's carcass has been deposited in the Herpetological Collection of the University of Nevada, Reno (UNR 7048). We thank A. Gubanich for identifying the hawk.

CROTALUS ATROX (Western Diamondback Rattlesnake). **MORPHOLOGY**. Painter et al. (1999. Herpetol. Rev. 30:44) reported congenital absence of the rattle in two specimens of *Crotalus atrox* from Eddy Co., New Mexico. Herein, I report two additional rattleless adult *C. atrox* collected from the San Simon Valley, Cochise Co., Arizona, USA, and deposited in the vertebrate collections at Arizona State University. One specimen (ASU 31401) lacks any evidence of a rattle, and has a short, abruptly tapered tail with no evidence of scarring or injury. The second specimen (ASU 31410) possesses a small, short, tapered segment ca. 2–3 mm in length. The segment is conical in shape, thus preventing formation

of an interlocking rattle string. These specimens were collected on 24 May 1997 (ASU 31401) and 27 July 1995 (ASU 31410) within 6 km of the intersection of Price Canyon Road and Arizona Hwy 80. Between 1993 and 1997 I observed 133 *C. atrox*, 343 *C. scutulatus*, and 123 *Sistrurus catenatus* near this site and these were the only rattleless individuals.

Submitted by **ANDREW T. HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA (e-mail: holycow@asu.edu).

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **MORPHOLOGY**. Painter et al. (1999. Herpetol. Rev. 30:44) report a rattleless female *Crotalus viridis viridis* that gave birth to a litter that included a rattleless neonate. Herein I report a rattleless female *C. v. viridis* with an abruptly tapered tail collected 20 September 1991 from a black-tailed prairie dog (*Cynomys ludovicianus*) town in south-central (T26N, R33W, S24) Cherry Co., Nebraska. Since there was no evidence of scarring or injury I concluded the condition was congenital. A photograph of the tail is provided in Holycross (1993. Movements and Natural History of the Prairie Rattlesnake, *Crotalus viridis viridis*, in the Sand Hills of Nebraska. Master's Thesis. Univ. of Nebraska, Lincoln. 88 pp.). I observed 157 *C. viridis* from this population during 1991 and this was the only rattleless individual.

Submitted by **ANDREW T. HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA (e-mail: holycow@asu.edu).

ECHINANTHERA AFFINIS (NCN). **DIET**. A young specimen of a neotropical colubrid snake, *Echinanthera affinis* (305 mm SVL, 105 mm tail length), was collected in a pitfall trap at the Parque Estadual do Ibitipoca (21°4'S, 43°52'W, ca. 1100 m elev), Municipality of Lima Duarte, State of Minas Gerais, Brazil, on 3 July 1997. We observed a tail tip in the snakes's mouth, and subsequently removed a young lizard, *Heterodactylus imbricatus* (44 mm SVL, 92 mm TL). Both specimens are deposited in the Museu Nacional-Rio de Janeiro collection (snake MNRJ 7306, lizard MNRJ 7307, verified by Ulisses Caramaschi).

In the intestines of the snake we also found some scales of *H. imbricatus*. The fact that this snake had already ingested another specimen of the same lizard species, at a different time, suggests that juvenile *E. affinis* commonly eat small lizards.

Submitted by **BERNADETE MARIA DE SOUSA**, Departamento de Zoologia, Instituto de Biociências, Universidade Federal de Juiz de Fora, Campus Universitário, Martelos, 36036-330 Juiz de Fora, MG, Brazil, and **CARLOS ALBERTO GONÇALVES DA CRUZ**, Departamento de Biologia Animal, Instituto de Biologia, UFRRJ, 23851-970 Seropédica, RJ, and Departamento de Vertebrados, Museu Nacional, Quinta da Boa Vista, 20940-040 Rio de Janeiro, RJ, Brazil (e-mail: cagcruz@uol.com.br).

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). **DIET**. *Elaphe guttata* is known to eat mammals, birds, lizards, and frogs (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Miffin Co., Boston, Massachusetts. 336 pp.; Degenhardt et al. 1996. Amphibians & Reptiles of New Mexico. University of New Mexico Press, Albuquerque, New Mexico. 430 pp.). On 19 March 1997 (0700–0720 h) we collected two male *Elaphe guttata emoryi* (768 and 704 mm SVL, 123.3 and 143 mm tail length (TL), 165.0 and 137.0 g, respectively) on the ground under logs of *Yucca* spp. at Las Norias del Refugio (22°55'26.1"N, 100°24'9"W; 1322 m elevation; xerophilic brushland), San Luis Potosí, México. Each snake had a *Sceloporus jarrovi minor* in its stomach. The lizard in the first snake measured 74.8 mm SVL, 50.5 mm TL, 9.0 g, and the lizard in the second snake measured 75.2 mm SVL, 48.3 mm TL, 8.0 g. Both lizards were female. The snakes and lizards are deposited in Colección Nacional de Anfibios y Reptiles del Instituto de Biología (IBH 12455-56), Universidad Nacional Autónoma de México.

We thank Héctor Hernández for his support, and Armando Borgonio for his logistic help. This study was supported by CONABIO Project No. R045/98.

FICIMIA HARDYI (Hooknose Snake). **REPRODUCTION**. Nothing is known about reproduction in *Ficimia hardyi*, a recently described snake from northern Hidalgo state, México (Mendoza-Quijano and Smith 1993. J. Herpetol. 27:406–410). On 15 March 1997, Carlos Gómez collected a gravid female *F. hardyi* that was deposited in Colección Nacional de Anfibios y Reptiles del Instituto de Biología, Universidad Nacional Autónoma de México (IBH-12454). The snake was caught in chaparral (1850 m elevation) at the San José de las Flores Ranch, ca. 17.5 km N of Guadalcázar, San Luis Potosí, México (22°44'17"N, 100°23'24"W). The female (276.0 mm SVL, 19.0 g) contained four eggs, which measured (mean ± SE): 14.2 ± 0.37 mm length; 6.1 ± 0.09 mm width; 0.31 ± 0.014 g. Relative clutch mass was 0.070 (Vitt and Price 1982. Herpetologica 38:237–255). This is the first record of reproduction in this species.

We thank Héctor Hernández for his support of this study, Hobart Smith for sending us literature, Armando Borgonio, Marcelino Espinosa, José Avila, and the authorities of the region for their logistic help, and Carlos Gómez and Rolando Bárcenas for their support in the field. Funding for this study was provided by CONABIO project # R045/98.

HAPSIDOPHRYS SMARAGDINUS (Emerald Snake). **EGGS.** Until now, there have been only two published accounts of egg-related data for *Hapsidophrys smaragdinus*. Schmidt (1923. Bull. Am. Mus. Nat. Hist. 49:1–146) records that a female *H. smaragdinus* collected in April 1914 in "Belgian Congo" contained three elongate eggs, 56 x 12 mm. Pitman (1974. A Guide to the Snakes of Uganda. Wheldon & Wesley, London. 294 pp.) records that a Ugandan specimen contained eggs 30 x 7 mm, but does not record their number or the time of year. Here, I report the number of eggs found in a third *H. smaragdinus*.

On 28 April 1986, a female *H. smaragdinus* was killed inside a house on the Southern Baptist Mission compound in Congotown, an area in the city of Monrovia, Liberia. The specimen, 87.5 cm total length, was brought to me. Dissection revealed that it was gravid with two eggs. I did not record their dimensions, but photographs of the specimen show that the eggs were about four times as long as wide, as in the previous reports of this species.

I thank Bob and Joan Juday for providing the specimen.

Submitted by **PHIL SENTER**, Department of Biological Sciences, Northern Illinois University, DeKalb, Illinois 60115, USA (e-mail: beccafaye@worldnet.att.net).

PHILOTHAMNUS HETERODERMUS (NCN). **DEFENSE.** Several species of the colubrid snake genus *Philothamnus* are known to inflate the neck when harassed (Marais 1992. A Complete Guide to the Snakes of Southern Africa. Krieger Publishing Company, Malabar, Florida. 208 pp.). Here, I record this behavior for the first time in *Philothamnus heterodermus*.

On 16 April 1987, I collected a live *P. heterodermus*, 58 cm total length, from a brush pile on the edge of a swamp behind House 4 of Area J, Yekepa, Nimba Co., Liberia. The snake was kept in a wood and screen cage for 44 days, after which it escaped. When first approached, the snake would cease motion. If further disturbed, it would inflate its throat, exposing black interstitial skin and a bright yellow spot on each dorsal scale. Each dorsal scale was green except for the yellow dot, which was covered by the adjacent scale when the neck was not inflated. Neck inflation thus transformed a solid green snake into a three-colored snake, as in *P. irregularis* and the closely-related *Hapsidophrys smaragdinus* (Senter 1999. Herpetol. Rev. 30:142). When handled, the snake bit. Dunger (1973. The Nigerian Field 38:158–180) records that the dorsal scale spots of *P. heterodermus* may be yellow in some specimens, but sky-blue or greenish blue in others.

Submitted by **PHIL SENTER**, Department of Biological Sciences, Northern Illinois University, DeKalb, Illinois 60115, USA (e-mail: beccafaye@worldnet.att.net).

PYTHON SEBAE (African Rock Python). **CAUDAL DISPLAYS.** Previous authors have recorded that *Python sebae* employs a defensive display which involves coiling the tail into a flat disk (Starin and Burghardt 1992. The Snake 24:50–62; Stemmler 1970. Salamandra 7:137–142). I have observed juvenile *P. sebae* exhibiting two different tail displays. These observations were made in the town of Yekepa, Nimba County, Liberia.

The first observation involved a captive snake that was crawling rectilinearly on a concrete porch when approached by a pet cat. The cat patted the snake's tail with a forepaw, and, in response, the python gathered its body together, drew its neck into an S-coil, ballooned its body to about twice its normal girth, and vibrated its tail violently in front of its face in the manner of a rattlesnake. Twice, the cat batted the python's vibrating tail with a forepaw. In response to each tail-batting, the python struck at the cat, though the cat jumped back too quickly to be bitten. After the second strike, the owner seized the snake and put it in its cage.

The snake was 66 cm in total length, just 5 cm longer than the average hatchling length given by Pitman (1974. A Guide to the Snakes of Uganda. Wheldon & Wesley, London. 290 pp.). The young age implied by the size of the snake suggests that its tail display behavior was innate, not learned, a suggestion that is supported by the owner's assertion that this was the snake's first contact with this cat. It is possible the captive snake was exhibiting behavior that a wild *P. sebae* might not exhibit. However, the snake had not been in captivity very long; according to the owner, it had been found in the bush in Montserrado Co., Liberia, only a few days before the incident.

Rapid tail vibration as an anti-predator device is widespread among caenophidians, especially colubrids and crotalines (Greene 1988. *In* Gans and Huey [eds.], Biology of the Reptilia Vol. 16, Ecology B, Defense and Life History, pp. 1–152. Alan R. Liss, New York, New York). Often, the tail is vibrated against some substrate, in order to produce a buzzing noise. This behavior has been interpreted as a means of avoiding being trampled by ungulates, or as a means of distracting a predator's attention from the snake's head (Greene, *op. cit.*). The scene which I report above suggests the latter interpretation for this behavior in *P. sebae*.

The second behavior was observed in two sibling *P. sebae* hatched in captivity at Steiner Zoo, Monrovia, Liberia. On several occasions during 1986–1988, I observed these two snakes wagging their tails as they crawled rectilinearly on the same porch. A stimulus for the tail-wagging was not apparent. The tail-wagging of these two pythons was slow and sinuous, as in the prey-luring tail-wag of *Chondropython viridis* (Murphy et al. 1978. J. Herpetol. 12:117–119). However, the *P. sebae* were not stationary, and it is therefore doubtful that they were attempting to lure prey.

The tails of snakes which caudally lure prey tend to have a color which differs from that of the rest of the body (Murphy et al., *op. cit*; Neill 1960. Quart. J. Florida Acad. Sci. 23:173–200). This contrast apparently helps to draw attention to the tail when the tail is moving. In *P. sebae*, the tail exhibits the same colors as the rest of the body, but its pattern is different. The tail of *P. sebae* exhibits a bold golden-yellow stripe which is set off by a dark brown border, while the snake's back exhibits a cryptic chain of dark brown blotches on a tan background. Though caudal luring has not been reported in this species, the boldness of the striped tail pattern and its contrast with the pattern on the rest of the body may function to fix a predator's attention on the tail. Such diversionary tail displays are recorded for members of most snake families (Greene, *op. cit.*).

I thank the owner of the pythons for access to them for observation.

Submitted by **PHIL SENTER**, Department of Biological Sciences, Northern Illinois University, DeKalb, Illinois 60115, USA (e-mail: beccafaye@worldnet.att.net).

SALVADORA GRAHAMAE LINEATA (Texas Patchnose Snake). **DIET**. Nothing is known about the food habits of *Salvadora grahamae lineata* in the wild. On 25 March 1997, we collected an adult male (Colección Nacional de Anfibios y Reptiles del Instituto de Biología, Universidad Nacional Autónoma de México, IBH-12453) *Salvadora grahamae lineata* (573 mm SVL, 129.5 mm tail length, 31.0 g) under a rock in grassland habitat on the road between Las Lagunas and La Noria de las Flores (22°40'46"N, 100°24'52"W, 2200 m elevation), San Luis Potosí, México. Dissection of the stomach revealed an adult *Sceloporus scalaris scalaris* (ca. 45 mm SVL, 5 g). The lizard was almost incomplete because of digestion. This is the first record of *Salvadora grahamae lineata* feeding on *Sceloporus scalaris scalaris* .

We thank the people of the region for their tremendous help during the field work. This study was supported by CONABIO Project No. R045/98.

Av. de los Barrios s/n, Los Reyes Iztacala, Tlalnepantla, Estado de México, C.P. 54090, A.P. 314, México; e-mail [ARB]: raurelio@servidor.unam.mx.

THAMNOPHIS CYRTOPSIS CYRTOPSIS (Western Blackneck Garter Snake). **BROOD SIZE**. Up to now nothing is known on reproduction of *Thamnophis cyrtopsis cyrtopsis* from México (Fitch 1970. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52:1–214; Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman, Oklahoma. 332 pp.). However, in *Thamnophis* from Texas, Arizona, and New Mexico brood sizes range from 3–22 young (Fitch, *op. cit.*; Rossman, *op. cit.*; Degenhardt et al. 1996. Amphibians & Reptiles of New Mexico. University of New Mexico Press, Albuquerque, New Mexico. 430 pp.). On 29 May 1999 at El Oro, Muncipality of Guadalcázar, San Luis Potosí, México, we captured a pregnant female *T. c. cyrtopsis* among rocks in chaparral-grassland (1800 m elevation). The snake was deposited in Colección Nacional de Anfibios y Reptiles del Instituto de Biología, Universidad Nacional Autónoma de México (IBH-12457). The snake (542 mm SVL, 207.7 mm tail length, 138.0 g) contained 9 well-developed embryos and 5 atretic follicles. Measurements of the embryos (mean ± SE, range) are as follows: mass 2.531 ± 0.138 g, 2.022–3.264, total length 19.6 ± 1.035 mm, 15.6–25.3. The relative litter mass (Vitt and Price. 1982. Herpetologica 38:237–255) was 0.1977.

We thank Hobart M. Smith for his tremendous help on this note, and Armando Borgonio, Marcelino Espinosa, and the authorities of the region for their logistic help. Funding for this study was provited by CONABIO Project No. R045/98.

TYPHLOPS DECORSEI (Decorse's Blind Snake). **MAXIMUM LENGTH**. Mocquard (1901. Bull. Mus. Natl. Hist. Nat. 7:251–255) reported a length of 455 mm for the holotype of *Typhlops decorsei*. Guibé (1958. Mém. Inst. Sci. Madagascar 12A:189–260) and Glaw and Vences (1994. A Field Guide to the Amphibians and Reptiles of Madagascar, 2nd ed. Privately Published. 350 pp.) list 455 mm as the maximum length. In January 1995, Frank Glaw collected and identified a *T. decorsei* at Kirindy (20°57'S, 44°13'E, 229 m), N Toliara Prov., W Madagascar that measures 600 mm in total length (preserved). This is a record size *T. decorsei* and the longest typhlopid known from Madagascar. The specimen is deposited in the Museum Alexander Koenig, Bonn, Germany (ZFMK 59793); identification was confirmed by Wolfgang Böhme.

Submitted by **VAN WALLACH**, Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138, USA; e-mail: vwallach@oeb.harvard.edu.

TYPHLOPS TASYMICRIS (Grenada Blind Snake). **MAXIMUM LENGTH** and **SECOND KNOWN SPECIMEN**. *Typhlops tasymicris* (Thomas 1974. Occ. Pap. Mus. Zool. Louisiana St. Univ. 46:1–5) has been known solely from the female holotype (Florida Museum of Natural History, Gainesville, UF/FSM 21547). A second and larger specimen (Museum of Vertebrate Zoology, Berkeley, MVZ 84060) from Pearl's Airport, St. Andrew Parish, Grenada (12°08'N, 61°37'W, elevation < 8 m), collected by J. F. Lynch (Field no. Y-25369) on 22 July 1968, was recently identified. It represents a range extension of 12 km NNW from the type locality. It agrees in most respects with the type specimen (20-20-20 scale rows, nasal divided, inferior suture contacting second supralabial, lacking postnasal concavity, one postocular, T-III supralabial imbrication pattern, parietals and occipitals transversely enlarged, 13 middorsal rows pigmented). Relevant data differing from the type are as follows (that of holotype given parenthetically): total length 196 (181) mm, tail length 2.5 (2.6) mm, tail/total length ratio 1.3% (1.4%), subcaudals 7 (5), total length/midbody diameter ratio 43.6 (47.6), and rostral/head width 0.5 (0.4). The specimen has only two teeth evident on each maxilla (possibly a third tooth has been shed on each side) and 3/5 undeveloped follicles are present in the left/right ovary.

I thank Emily N. Taylor and J. A. Rodríguez-Robles for loan of the specimen and permission to examine its viscera.

Submitted by **VAN WALLACH**, Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138, USA; e-mail: vwallach@oeb.harvard.edu.

UROMACERINA RICARDINII (Vine Snake). **PREDATION AND PREY**. Vine snakes display morphological features related to arboreal habits, including a very slender body and long tail (Henderson and Bider 1980. Milwaukee Publ. Mus. Contr. Biol.

(Henderson and Bider 1980. Milwaukee Publ. Mus. Contr. Biol. Geol. 37:1–38). All vine snakes are primarily arboreal and feed mainly on lizards (Henderson and Bider, *op. cit.*). *Uromacerina ricardinii* is a cryptically colored vine snake that occurs mainly in the Atlantic Forest in southeastern Brazil (Cunha and Nascimento 1982. Bol. Mus. Par. Emilio Goeldi, n.s. Zool. 113:1–9). Amaral (1978. Serpentes do Brasil. Melhoramentos/Univ. São Paulo, Brazil, 246 pp.) mentions that *U. ricardinii* is arboreal and preys on lizards. Here, I report the gut contents of the three specimens housed in the collection of the Instituto Butantan (IB), and an observation of predation on this snake.

An adult female (IB 42061, 40.5 mm SVL, 33 mm tail length) contained one semi-digested treefrog (*Hyla* sp.). Another female (IB 34412, 435 mm SVL, 360 mm tail length) contained the legs of a hylid treefrog. A third snake (IB 45178, 315 mm SVL, 305 mm tail length) had insect remains in its hindgut, possible due to secondary ingestion. One adult male (IB 25120, 420 mm SVL, 325 mm tail length) collected by W. Grantsau was found in the stomach of a mantled hawk (*Leucopternis polionota*). This forest hawk is reported to feed on arthropods and small snakes (Sick 1984. Ornitologia Brasileira, vol I, Editora UNB, Brasil, 481 pp.). The data here do not support the assertion of Amaral (*op. cit.*) that this snake is a lizard specialist. At the very least, *U. ricardinii* also regularly preys on hylids. Additionally, despite its camouflage, *U. ricardinii* at least occasionally falls prey to forest hawks.

I thank I. Sazima for reviewing the manuscript.

Submitted by **OTAVIO A. V. MARQUES**, Laboratório de Herpetologia, Instituto Butantan, Av. Vital Brazil, 1500, CEP 05503-900, São Paulo, SP, Brazil (e-mail: otaviomarques@originet.com.br).

PSEUDACRIS CRUCIFER (Spring Peeper). USA: ILLINOIS: DEKALB CO: Mayfield Twp. (Sec. 21, T41N, R4E). 21 April 2000. Wilkinson-Renwick marsh edge observation by KS on 20 June 2000, and voucher specimen collected by HDW. HDW-NIU 1678. Verified by Dale Saar. New county record; range extension from the closest localities in Ogle County and an earlier observation in Winnebago County (Smith 1961, Bull. Illinois Nat. Hist. Surv. 28:1–298; Phillips et al. 1999, Illinois Nat. Hist. Surv. Manual 8:1–282.

Submitted by **HARLAND D. WALLEY** and **KRISTIN STANFORD**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

RANA MIOPUS (Three-striped Frog). MALAYSIA: PENINSULAR MALAYSIA: TERENGGANU: Sekayu Waterfalls (04°58'N, 102°58'E). 18 March 1992. Peter K. L. Ng et al. Raffles Museum of Biodiversity Research, Zoological Reference Collection (ZRC.1.3063, SVL 41.7 mm). Verified by Kelvin K. P. Lim. New state record (Berry 1975, The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp.).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260.

SCAPHIOPUS HOLBROOKII HURTERII (Hurter's Spadefoot). USA: LOUISIANA: Vernon Parish: Fort Polk Military Reservation area, 0.5 mi W jct. Artillery Road and Cole Road. 3 April 2000. Dave E. Plair and Ken Moore. Seale Museum of Louisiana, McNeese State University (SML 9322). Verified by Jeff Boundy. First parish record; extends distribution south from Sabine and Natchitoches Parishes and west from Rapides Parish as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA, and **BEAU B. GREGORY**, Environmental and Natural Resource Management Division, Directorate of Public Works, Fort Polk, Louisiana 71459, USA.

TELMATOBIUS CARRILLAE (Ancash Water Frog). PERU: HUANUCO: PROVINCIA DOS DE MAYO: Baños, Caserio de Rio Blanco (10°05'S, 76°46'W, 4000 m elev.). 14 October 1998. E. Lehr. Natur-Museum und Forschungs-Institut Senckenberg (SMF 80531–38). Verified by Javier Icochea. First record for state of Huanuco and southernmost for Peru (Morales 1988, Revta Bras. Zool. 5:603–608; Rodríguez et al. 1993, Publ. Mus. Hist. Nat. UNMSM [A] 45:1–22).

Submitted by **EDGAR LEHR**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a. M., Germany (e-mail: elehr@sng.uni-frankfurt.de) and **EMILIO FUENTES**, Museo de Historia Natural, Departamento de Herpetologia, Universidad Nacional Mayor de San Marcos, Avenida Arenales 1256, Jesus Maria, Apartado 14-0434, Lima, Peru.

TESTUDINES

APALONE SPINIFERA SPINIFERA (Eastern Spiny Softshell). USA: NORTH CAROLINA: ROCKINGHAM CO: 4 km SW Stoneville

near Mayo River. 8 September 1998. F. Gann and T. Martin. North Carolina State Museum of Natural Sciences (NCSM 60382). Verified by William M. Palmer. New county record. First record for Roanoke (Dan) River drainage (Palmer and Braswell 1995, Reptiles of North Carolina. Univ. North Carolina Press, Chapel Hill. xiii + 412 pp.). May represent an introduction; survey work should be undertaken to verify the presence of a native population in this drainage. The specimen, an adult male, is apparently also of record size, measuring 310 mm CL. Conant and Collins (1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Exp. Houghton Mifflin Co., Boston, Massachusetts. xviii + 616 pp.) reported a maximum size of 235 mm.

Submitted by **ANN B. SOMERS**, Department of Biology, P.O. Box 26174, University of North Carolina at Greensboro, Greensboro, North Carolina 27402-6174, USA, **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Research Laboratory, 4301 Reedy Creek Road, Raleigh, North Carolina 27607, USA and **DENNIS W. HERMAN**, North Carolina State Museum of Natural Sciences, 11 West Jones Street, Raleigh, North Carolina 27601, USA.

CHELYDRA SERPENTINA (Common Snapping Turtle). USA: FLORIDA: Franklin Co: St. George Island, St. George Island State Park. 7 January 2000. L. K. Irwin and K. J. Irwin. Verified by Joseph T. Collins. KU Color Slide 11774. Adult photographed while basking in fresh water pond, directly adjacent to bay side of coastal dunes. First record for St. George Island and Apalachicola Bay Barrier Islands (Blaney 1971, Herpetologica 27:406–430; Means 1974, *In* Livingston et al. [eds.], St. George Island: Biota, Ecology, and Management Program for Controlled Development. Rept. Develop. Regional Impact Franklin County Commission).

Submitted by **LISA K. IRWIN**, Clemson Institute of Environmental Toxicology, 509 Westinghouse Road, Pendleton, South Carolina 29670, USA, and **KELLY J. IRWIN**, Arkansas Game & Fish Commission, Nongame Aquatics Program, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us).

CHELYDRA SERPENTINA (Common Snapping Turtle). USA: WISCONSIN: Green Co: Brodhead, Route 11 at jct. with Sugar River, Decatur Twp., Sec 11 T1N, R10E. 4 June 2000. Harlan D. Walley. HDW-NIU 1680. Verified by Dayle Saar. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Interim Report Wisconsin Herpetological Atlas Project, Milwaukee Public Museum. 87 pp.).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois, Dekalb, Illinois 60115, USA.

GRAPTEMYS GEOGRAPHICA (Common Map Turtle). USA: WISCONSIN: Crawford Co: Spring Lake, Ambrough Slough. Sec. 36, T96N, R3W. 21 June 2000. Harlan D. Walley and William Peterson. HDW-NIU 1681. Verified by Joseph T. Collins. Gravid female, DOR. Casper (1997, Herpetol. Rev. 28:216) cited a USNM specimen collected from Crawford County, Prairie du Chien, in August 1927. The specimen reported herein represents the first record from the county since the 1927 record, and verifies its presence there.

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

PHRYNOPS VANDERHAEGEI (Vanderhaege´s Toadhead Turtle). ARGENTINA: MISIONES: Departamento Capital: Villa Lanus, Posadas (27°27'S, 55°53'W). 15 September 1992. D. Baldo. Herpetological collection of Fundación Miguel Lillo, Tucumán, Argentina (FML 09381). Verified by E. Richard. First voucher specimen with precise locality for Misiones province and second record from Argentina, where its presence was previously reported by Iverson 1986 (A Checklist with Distribution Maps of the Turtles of the World. Privately printed. Richmond, Indiana. 229 pp.) and Waller and Chébez (1987, Hist. Nat. 7:56).

Submitted by **DIEGO BALDO** and **ERNESTO KRAUCZUK**, Laboratorio de Citogenética General, Departamento de Genética, Facultad de Ciencias Exactas Químicas y Naturales, Universidad Nacional de Misiones, Félix de Azara 1552, 3300 Posadas, Misones, Argentina (e-mail: diegobaldo@hotmail.com).

PSEUDEMYS CONCINNA (Eastern River Cooter). USA: KENTUCKY: Muhlenberg Co: adult male alive on county road ca. 6.4 km ENE Central City, 0.4 km W Nelson and 1.5 km W Green River. 11 October 1999. Michael J. Lodato. CMNH Photo Voucher Accession 36628). Verified by John McGregor. New county record; confirms presence of this turtle in middle/lower reaches of Green River (John McGregor, pers. comm.).

Submitted by **MICHAEL J. LODATO** and **PATRICIA J. LODATO**, 925 Park Plaza Drive, Evansville, Indiana 47715, USA.

STERNOTHERUS ODORATUS (Common Musk Turtle). USA: KANSAS: Leavenworth Co: backwater 0.5 mi NE railroad crossing on Leavenworth County Road 1, N of Eudora, N38.9775, W95.0874. 12 June 2000. John Tollefson, David Edds and Kyle Edds. KU Color Slides 11775-776 (photographed by Suzanne L. Collins). Verified by Joseph T. Collins. First record for county (Collins 1993, Amphibians and Reptiles in Kansas. Third Edition. Univ. Press Kansas, Lawrence. xx + 397 pp.).

Submitted by **JOHN TOLLEFSON**, Department of Biological Sciences, Emporia State University, Emporia, Kansas 66801, USA.

LACERTILIA

CNEMIDOPHORUS SACKII (Sack's Spotted Whiptail). MEXICO: MEXICO: Municipality of Malinalco (18°52'N, 99°27'W), 1600 m. 6 July 1996. Rodolfo García Collazo, Claudia Valdespino Torres, Isabel Mercado, and Arturo Morales Gutiérrez. Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México. (IBH 12301–302). Verified by Aurelio Ramírez-Baustista. First record for the state of México: extends range 14 km S from the closest known locality in Coatlán del Río, Morelos (Castro y Aranda 1984, Estudio Preliminar sobre la Ecología de los Reptiles del Estado de Morelos. Tesis Licenciature, Escuela de Ciencias Biológicas, UAEM: 61).

Submitted by **CLAUDIA S. VALDESPINO** and **RODOLFO GARCÍA-COLLAZO**, Laboratorio de Zoología, Escuela Nacional de Estudios Profesionales Campus Iztacala, Universidad Nacional Autónoma de México, Avenida de los Barrios s/n, Los

Reyes Iztacala, Tlanepantla, Estado de México, Caixa Postal 54090, Apartado Postal 314, México.

HEMIDACTYLUS FLAVIVIRIDIS (Indian Leaf-toed Gecko). EGYPT: ISMAILIA PROVINCE: Ismailia City, Area No. 6 (30°35'41"N, 32°18'26"E). 8 July 1999. Adel A. Ibrahim. Museum National d'Histoire Naturelle, Paris (MNHN 2000.2509). Verified by Ivan Ineich. A subadult female (56 mm SVL) captured at 2130 h on the fence of the Suez Canal Authority Hospital, immediately adjacent to the Suez Canal. First record for Ismailia Province (Saleh 1997, Amphibians and Reptiles of Egypt. Publ. National Biodiversity Unit. No. 11:1–234). In Egypt, this species has been previously recorded from the city of Suez, the southern terminus of the Suez Canal, and Qusair on the Red Sea (Anderson 1898, Zoology of Egypt. Reptilia and Batrachia. Quaritch, London. Vol. I. 370 pp.).

Submitted by **ADEL A. IBRAHIM**, Department of Biological Sciences and Geology, Faculty of Education at Al-Arish, Suez Canal University, North Sinai, Egypt (e-mail: aibrahim@ismailia.ie-eg.com).

LIOLAEMUS FITZGERALDI. ARGENTINA: SAN JUAN: Calingasta Department: 130 km from city of San Juan on Quebrada de las Cortaderas, Río Castaño (30°57'S, 69°32'W). March 1999. J. C. Acosta, G. Ortiz, and F. Murúa. Herpetological Collection, Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Argentina (IMCN-UNSJ 399–400). Verified by Luciano Avila. Extends the known range (Avila et al. 1998, Cuad. Herpetol. 12[1]:11–29) ca. 120 km NE of nearest locality (El Pachón, Calingasta Department, San Juan Province).

Submitted by **JUAN CARLOS ACOSTA**, **GRISEL ORTIZ**, and **FERNANDO MURÚA**, Departamento de Geofísica y Astronomía e Instituto y Museo de Ciencias Naturales, F. C. E. F. y N., Universidad Nacional de San Juan, Avenida España 400 (N), Caixa Postal 5400, San Juan, Argentina (e-mail [JCA]: jcacosta@impsat1.com.ar).

SCELOPORUS GADOVAE (Gadow's Spiny Lizard). MEXICO: MEXICO: Municipality of Malinalco (18°52'N, 99°26'W), 1580 m. 6 July 1996. Rodolfo García Collazo. Coleccíon Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México (IBH 12303–04); Municipality of Zumpahuacan (18°50'N, 99°33'W), 1850 m. 16 May 1997. Rodolfo García Collazo and Claudia S. Valdespino Torres. IBH 12305. Both verified by Aurelio Ramírez Bautista. First records for the state of México; extends range at least 15.5 km SW from the closest known locality in Coatlán del Río, Morelos (Castro y Arando 1984, Estudio Preliminar sobre la Ecología de los Reptiles del Estado de Morelos. Tesis Licenciatura, Escuela de Ciencias Biológicas, UAEM: 118).

Submitted by **CLAUDIA S. VALDESPINO** and **RODOLFO GARCÍA-COLLAZO**, Laboratorio de Zoología, Escuela Nacional de Estudios Profesionales Campus Iztacala, Universidad Nacional Autónoma de México, Avenida de los Barrios s/n, Los Reyes Iztacala, Tlanepantla, Estado de México, Caixa Postal 54090, Apartado Postal 314, México.

STENODACTYLUS STHENODACTYLUS STHENODACTYLUS (Elegant Gecko). EGYPT: ISMAILIA PROVINCE: ca. 15 km SE Ismailia City (vicinity of Tosson), Ismailia-Suez Canal Highway, 30°29'38"N, 32°20'20"E. 1 May 2000. Adel A. Ibrahim. Museum National d'Histoire Naturelle, Paris (MNHN 2000.2511). Verified by Ivan Ineich. AOR adult female (53 mm SVL) collected at 2200 h. First record for Ismailia Province and the Suez Canal Zone (Saleh 1997, Amphibians and Reptiles of Egypt. Publ. National Biodiversity Unit. No. 11:1–234). Species is widely distributed in the eastern and western deserts of Egypt, desert margins of the Nile River, and the western coasts of the Gulf of Suez and the Gulf of Aqaba (Flower 1933, Proc. Zool. Soc. London 1[4]:735–851).

Submitted by **ADEL A. IBRAHIM**, Department of Biological Sciences and Geology, Faculty of Education at Al-Arish, Suez Canal University, North Sinai, Egypt (e-mail: aibrahim@ismailia.ie-eg.com).

TARENTOLA ANNULARIS ANNULARIS (Ringed Wall Gecko). EGYPT: ISMAILIA PROVINCE: ca. 1.5 km N Ismailia City, Suez Canal University Old Campus (30°36'19"N, 32°18'22"E). 16 July 1999. Adel A. Ibrahim. Museum National d'Histoire Naturelle, Paris (MNHN 2000.2510). Verified by Ivan Ineich. Adult female (85 mm SVL) captured from a building on campus at 2045 h. Species was subsequently found to inhabit all buildings of the Suez Canal University Old Campus. First province record (Saleh 1997, Amphibians and Reptiles of Egypt. Publ. National Biodiversity Unit. No. 11:1–234).

Submitted by **ADEL A. IBRAHIM**, Department of Biological Sciences and Geology, Faculty of Education at Al-Arish, Suez Canal University, North Sinai, Egypt (e-mail: aibrahim@ismailia.ie-eg.com).

TUPINAMBIS RUFESCENS (Red Tegu). ARGENTINA: SAN JUAN: Caucete Department: 42 km from city of San Juan on Puesto de Narváez, Km 202, Ruta Nacional 141 (31°11'S, 68°10'W). December 1999. F. Gallego, P. F. Gomez, J. C. Acosta, and R. Martori. Herpetological Collection, Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Argentina (IMCN-UNSJ 456, juv.). Verified by Ricardo Martori. Extends known range (Cei 1993, Mon. XIV Mus. Reg. Sci. Nat. Torino. 949 pp.) ca. 93 km W of nearest known locality (Marayes, Caucete Department, San Juan Province).

Submitted by **JUAN CARLOS ACOSTA** and **PABLO GOMEZ**, Departamento de Geofísica y Astronomía e Instituto y Museo de Ciencias Naturales, F. C. E. F. y N., Universidad Nacional de San Juan, Avenida España 400 (N), Caixa Postal 5400, San Juan, Argentina (e-mail [JCA]: jcacosta@impsat1. com.ar).

SERPENTES

GEOPHIS CHALYBEUS (Veracruz Earth Snake). MEXICO: VERACRUZ: Cerro Aquila, Municipality of Aquila (18°47'39"N, 97°18'27"W), 1800 m elev. Oak forest. 23 October 1998. Collected by Miguel Angel de la Torre Loranca. Estacion de Biología Tropical Los Tuxtlas (UNAM-LT 3337). Verified by Gonzalo Pérez-Higareda. First record with precise locality for the state of Veracruz; previous records were not accurate (Pelcastre-Villafuerte and Flores-Villela 1992, UNAM Publ. Esp. Mus. Zool. 4:25–96). This record is 90 km (airline) NNE (20°) from locality "Xalapa"

(Pérez-Higareda and Smith 1991, Ofidiofauna de Veracruz. Instituto de Biología, Universidad Nacional de México, Publicaciones Especiales 7:1–122).

Submitted by **MIGUEL A. DE LA TORRE-LORANCA** and **MARCO ANTONIO LÓPEZ-LUNA**, Centro de Investigaciones Herpetologicas de Veracruz A. C. Apartado Postal 473, Caixa Postal 95500, Cordoba, Veracruz, Mexico (e-mail: cihvac@correoweb.com), and **RICHARD C. VOGT**, Estacíon de Biología Tropical Los Tuxtlas, Apartado Postal 91, Caixa Postal 95700 San Andres Tuxtla, Veracruz, México (e-mail: dickturtle@aol.com).

HYDROPS TRIANGULARIS (Triangle Water Snake). VENEZUELA: COJEDES: Municipio Rómulo Gallegos: Asentamiento La Blanca, sector Rincón Moreno, SW San Carlos City (09°34'18"N, 68°37'14"W), 140–150 m elev. 1996 (date not recorded). Numa Hurtado. Museo de Biología, Universidad Central de Venezuela (MBUCV) 7117. Verified by César R. Molina. First state record and northernmost locality for the species. Widely distributed in South America, in northern cis-Andean regions of Colombia, Venezuela, Guyanas, Brazil, Bolivia, Peru, Paraguay, Ecuador, and the island of Trinidad (Kornacker 1999, Checklist and Key to the Snakes of Venezuela. PaKo-Verlag. 270 pp.). Only one subspecies (*H. t. venezuelensis)* has been described for Venezuela (Roze 1957, Acta Biol. Venezuela 2[8]:51–95). Specimen differs from this subspecies in having a higher subcaudal scale count (69 as compared to 37 in *H. t. venezuelensis*). In this respect, it is closer to *H. t. neglectus* from Trinidad and Guyana. Conversely, the presence of 46 black dorsal bands and 11 black caudal bands is similar to counts for *H. t. fasciatus* and *H. t. triangularis*. Due to this uncertainty of subspecific allocation, we prefer to use only the binomial, pending future detailed studies. Similar uncertainties in the recognition of subspecies in *Hydrops triangularis* based on current recognized characters have also been noted by other authors (e.g., Chippaux 1986, Les Serpents de la Guyane Française. Edition de l'ORSTOM. 165 pp.; Rufino 1999, Analisis Comparativa de *Hydrops triangularis triangularis* [Wagler, 1824] e *Hydrops triangularis fasciatus* [Gray, 1824]. V Congreso Latinoamericano de Herpetologia. Publ. Extra Mus. Nac. Hist. Nat. Montevideo- Uruguay 50:104).

Submitted by **GILSON RIVAS FUENMAYOR**, Fundación La Salle de Ciencias Naturales, Estación de Investigaciones Agropecuarias, Avenida Bolívar 20-1219, San Carlos 2201, Estado Cojedes, Venezuela (e-mail: gilsonrivas@mixmail.com), and **OSWALDO FUENTES**, Instituto de Medicina Tropical-Serpentarium, Apartado Postal 47423, Caracas 1041, Venezuela (e-mail: ofuentes@tyto.ciens.ucv.ve).

LAMPROPELTIS TRIANGULUM MULTISTRIATA (Pale Milk Snake). USA: NEBRASKA: Garden Co: 28.7 km N of Rt. 26 (by Road 181 from Oshkosh), 200 m W Road 181 (41°39'N, 102°21'W, elev. 1143 m) on rocky outcrops near Blue Creek. 30 July 1998. S. J. Converse. Florida Museum of Natural History (UF 120808). Verified by J. B. Iverson; 1.6 km SE of Windlass Hill, Ash Hollow State Park (two specimens). 16 May 1976. J. B. Iverson. UF 116210–211. Verified by K. L. Krysko. New county record (Lynch 1985, Tran. Nebraska Acad. Sci. 13:33–57).

Submitted by **SARAH J. CONVERSE**, Department of Fishery and Wildlife Biology, Colorado State University, Ft. Collins, Colorado, 80523-1474, USA, and **DEBRA S. BAKER**, Natural History Museum and Biodiversity Center, University of Kansas, Lawrence, Kansas 66045-2454, USA.

LEPTOTYPHLOPS ALBIFRONS (Wagler's Blind Snake). PERU: PASCO: Provincia Oxapampa: Pozuzo (10°04'S, 75°33'W, 770 m elev.). 30 April 1995. R. Cielos. Collection of the Centro de Salud San Camilo Pozuzo (PE 1169–71) and photograph vouchers Natur-Museum und Forschungs-Institut Senckenberg (SMF-F 220–22). Verified by Nelly Carrillo de Espinoza. First record for state of Pasco (Carrillo de Espinoza and Icochea 1995, Publ. Mus. Hist. Nat. UNMSM [A] 49:1–27).

Submitted by **EDGAR LEHR**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a.M., Germany (e-mail: elehr@sng.uni-frankfurt.de).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). MEXICO: MEXICO: Municipality of Tenancingo (18°56'28"N, 99°36'W), 2000 m. 15 May 1997. Claudia S. Valdespino Torres. Coleccíon Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México. (IBH 11307). Verified by Aurelio Ramírez-Bautista. First record for the state of México. Specimen was found in recently turned earth near a flower market. Previously, Mexican records were based on specimens from introduced populations in Baja California Sur (Murphy and Ottley 1979, Herpetol. Rev. 104:119), Sinaloa, Michoacán, and Guerrero on the Pacific Coast, and inland from Querétaro and Morelos (Dixon and Hendricks 1979, Zool. Verhandelingen 173:1–39), Jalisco (Dundee and Flores-Villela 1991, Herpetol. Rev. 22:26), Veracruz (Mendoza et al. 1993, Herpetol. Rev. 24:110), Oaxaca (Mendoza and Rendón 1994, Herpetol. Rev. 25:34), Puebla (Eliosa et al. 1995, Herpetol. Rev. 26:110), Nuevo León (Alvarez and Lurillo 1996, Vert. Mexicana 2:1–2).

Submitted by **CLAUDIA S. VALDESPINO** and **RODOLFO GARCÍA-COLLAZO**, Laboratorio de Zoología, Escuela Nacional de Estudios Profesionales Campus Iztacala, Universidad Nacional Autónoma de México, Avenida de los Barrios s/n, Los Reyes Iztacala, Tlanepantla, Estado de México, Caixa Postal 54090, Apartado Postal 314, México.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). MEXICO: VERACRUZ: Municipality of San Andres Tuxtla (18°26'8"N, 95°12'58"W), 300 m elev. 15 November 1998. Collected by Miguel Angel de la Torre Loranca. Estacíon de Biología Tropical Los Tuxtlas (UNAM-LT 3338). Verified by Gonzalo Pérez-Higareda. Second record for the state and range extension of 128 km (airline) NW (307°) from Playa Mocambo (Mendoza-Quijano et al. 1993, Herpetol. Rev. 24:110).

Submitted by **MIGUEL A. DE LA TORRE-LORANCA** and **MARCO A. LÓPEZ-LUNA**, Centro de Investigaciones Herpetologicas de Veracruz A. C. Apartado Postal 473, Caixa Postal 95500, Cordoba, Veracruz, Mexico (e-mail cihvac@correoweb.com), and **RICHARD C. VOGT**, Estacíon de Biología Tropical Los Tuxtlas, Apartado Postal 91, Caixa Postal 95700 San Andres Tuxtla, Veracruz, México (e-mail: dickturtle@aol.com).

REGINA RIGIDA (Glossy Crayfish Snake). USA: FLORIDA: FRANKLIN Co: St. Vincent Island National Wildlife Refuge at jct. Roads D & 4. 14 January 2000. Thomas E. Lewis. Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas (MHP 6733). Verified by Travis W. Taggart. First record for island [Blaney 1971, Herpetologica 27:406–430].

Submitted by **THOMAS E. LEWIS**, St. Vincent National Wildlife Refuge, P.O. Box 447, Apalachicola, Florida 32329, USA, and **JOSEPH T. COLLINS**, The Center for North American Amphibians and Reptiles, 1502 Medinah Circle, Lawrence, Kansas 66047, USA.

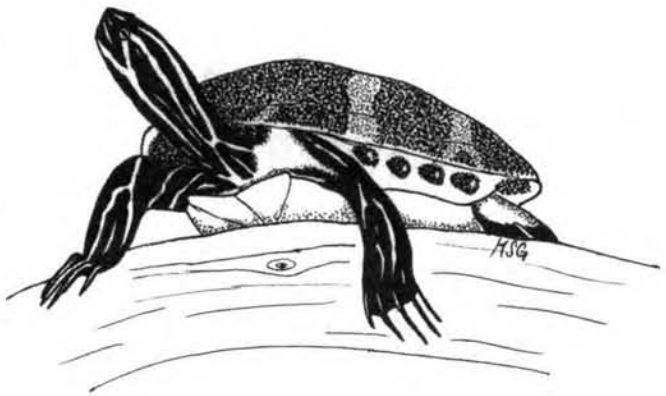
TACHYMENIS PERUVIANA (Peru Slender Snake). PERU: HUANUCO: PROVINCIA PACHITEA: Chaglla (09°50'S, 75°54'W, 2980 m elev.). 18 August 1998. E. Lehr. Museo de Historia Natural de San Marcos (MHNSM 20062). Verified by Nelly Carrillo de Espinoza. First record for state of Huanuco (Carrillo de Espinoza and Icochea 1995, Publ. Mus. Hist. Nat. UNMSM [A] 49: 1–27).

Submitted by **EDGAR LEHR** and **GUNTHER KÖHLER**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a. M., Germany (e-mail [EL]: elehr@sng.uni-frankfurt.de).

TAENIOPHALLUS AFFINIS (NCN). BRAZIL: ALAGOAS: Murici Forest, Fazenda Bananeiras (09°14'S, 35°48'W). 27 May 1995. Museu de História Natural, Universidade Federal de Alagoas (MUFAL 1663); Salva Forest, Rio Largo (09°30'S, 35°50'W) in small patches of Atlantic Forest. 5 May 1995. MUFAL 1664. Eliza M. X. Freire, Selma T. Silva, and Jorge L. Lopes. PARAÍBA: Mamanguape, Guaribas Reserve (06°45'S, 35°07'W). 25 November 1999. Universidade Federal da Paraíba (UFPB 2384); 10 December 1999. UFPB 2385. Selma T. Silva. All verified by Marcos Di-Bernardo. First records for the north Atlantic Forest; extend the known range ca. 1350 km N of Espirito Santo, Brazil (Di-Bernardo 1992, Comunic. Mus. Ciênc. PUCRS 5[13]:225–256) and 920 km NE from Vitória da Conquista, Bahia, Brazil (Argôlo 1998, Herpetol. Rev. 29:176).

Submitted by **ELIZA MARIA XAVIER FREIRE** and **SELMA TORQUATO DA SILVA**, Departamento de Zoologia and Museu de História Natural, Universidade Federal de Alagoas, Rua Aristeu de Andrade, 452, Farol, Maceió, Alagoas, 57021-090, Brazil.

TANTILLA YAQUIA (Yaqui Blackhead Snake). USA: NEW MEXICO: Hidalgo Co: along New Mexico Rt. 9, 8 km E jct. with I-80. 25 September 1999. 1857 h. Michael D. Wilcox and Denise A. Wilcox. MSB 61412 and LACM Color Slide PC-1335. Verified by D. A. Kizirian. Extends known range in New Mexico ca. 43.5 km N and 8.1 km E of previous known records (McDiarmid 1977, Cat. Am. Amph. Rept. 198:1–2; Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 430 pp.). Occurs sympatrically with *T. hobartsmithi and T. nigriceps* in this area.



Submitted by **MICHAEL D. WILCOX**, Ogden Environmental and Energy Services, 3120 Chicago Avenue, Suite 180, Riverside, California 92507, USA, **DENISE A. WILCOX**, Western University of Health Sciences, 309 East Second Street, College Plaza, Pomona, California 91766, USA, **KENT R. BEAMAN**, Section of Herpetology, Natural History Museum of Los Angeles County, 900 Exposition Boulevard, Los Angeles, California 90007, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

TANTILLITA LINTONI ROZELLAE (Rozella's Dwarf Shorttailed Snake). MEXICO: VERACRUZ: Municipality of Tezonapa, G. Vázquez-Vela Ejido (18°39'04"N, 96°47'20"W), elev. 550 m, and Loma Buena Vista Ejido (18°39'10"N, 96°47'29"W), elev. 500 m. 21 July 1997. Collected by Roberto Mora Gallardo. Estación de Biología Tropical "Los Tuxtlas", Instituto de Biologia, Universidad Nacional Autonoma de México (UNAM-LT 3350, UNAM-LT 3335 respectively). Verified by Gonzalo Pérez-Higareda. Characters are the same as those described in Pérez-Higareda G. (1985, Bull. Maryland Herpetol. Soc. 21:38–40). Range extension of 180 km NW from the only previously known locality in Sierra de Los Tuxtlas (Pérez-Higareda and Smith 1991, Ofidiofauna de Veracruz. Instituto de Biología, Universidad Nacional de México, Publicaciones Especiales 7:1–122).

The herpetofauna of the southeastern Peruvian rainforest is still relatively unknown; a small number of short-term studies have produced preliminary inventories of some sites but, until recently, no long-term censuses had been conducted. Previous inventory lists for four sites in the Tambopata Province have been written: Cusco Amazónico (Duellman and Salas 1991), Explorer's Inn (McDiarmid and Cocroft 1995), Sachavacayoc Centre (Sehgelmeble 1997), and Tambopata Research Center (Salas 1995). Recently, we have completed an intensive study that took place from January 1997 to November 1998 at six localities within the Tambopata Province, Department of Madre de Dios. This study revealed seven species not previously recorded in the Tambopata Province and many other species that had not been recorded for the sampled localities. Voucher specimens are deposited in the Museo de Historia Natural, Universidad de San Antonio Abad del Cusco, Perú (MHNUNSAAC; specimens of that Museum retain original field codes, therefore all specimens collected by us bear the code PT). All specimens were verified by Oscar Ochoa Mendieta.

Hyla triangulum (Triangle Treefrog). TAMBOPATA PROVINCE: EcoAmazonía, 35.2 km ENE Puerto Maldonado (12°31'44"S, 68°55'58"W). 6 June 1997. Margaret Bartee. MHNUNSAAC PT 232. An adult male specimen was found at night perched on a leaf at 40 cm off the ground. First record for Provincia Tambopata. Previously recorded in Estación Biológica de Cocha Cashu, Provincia Manu, Departamento de Madre de Dios, 297 km to the WNW (Rodríguez and Cadle 1990).

Amphisbaena fuliginosa (Mottled Amphisbaena). TAMBOPATA PROVINCE: Explorer's Inn, 30 km SSW Puerto Maldonado (12°50'18"S, 69°17'45"W). March 1997. Tiffany M. Doan. MHNUNSAAC PT 514. Specimen was found crawling along a trail during the morning. First record for Departamento de Madre de Dios. Previously recorded from the departments of Amazonas, Cusco, Loreto, and Ucayali, a minimum extension of 318 km to the WSW (Cusco) (Carrillo and Icochea 1995).

Anolis nitens (Matinga Anole). TAMBOPATA PROVINCE: EcoAmazonía, 35.2 km ENE Puerto Maldonado (12°31'44"S, 68°55'58"W). 6 June 1997. Wilfredo Arizábal Arriaga. MHNUNSAAC PT 234. One of four species of *Anolis* in Provincia Tambopata, this lizard is very uncommon and most easily captured at night while it sleeps on green leaves ca. 1 m above the forest floor. First record for Provincia Tambopata. Previously reported from Estación Biológica de Cocha Cashu, Provincia Manu, Departamento de Madre de Dios, ca. 290 km to the WNW (Rodríguez and Cadle 1990).

Atractus badius (Earthsnake). TAMBOPATA PROVINCE: Cusco Amazónico, 15 km ENE Puerto Maldonado (12°32'28"S, 69°03'36"W). April 1997. Wilfredo Arizábal Arriaga. MHNUNSAAC PT 182; Sachavacayoc Centre, 35 km SSW Puerto Maldonado (12°51'10"S, 69°21'57"W). 23 November 1997. Tiffany M. Doan. MHNUNSAAC PT 377; EcoAmazonía, 35.2 km ENE Puerto Maldonado (12°31'44"S, 68°55'58"W). 18 March 1998. Wilfredo Arizábal Arriaga. MHNUNSAAC PT 222; Tambopata Research Center, 86.5 km SSW Puerto Maldonado (13°08'53"S, 69°37'02"W). 15 February 1998. José Antonio Ochoa Cámara. MHNUNSAAC PT 422. All individuals were captured on the forest floor at night. First records for Departamento de Madre de Dios. Previously recorded in the department of Loreto, 1099 km to the north (Carrillo and Icochea 1995).

Ninia hudsoni (Amazon Coffee Snake). TAMBOPATA PROVINCE: Tambopata Research Center, 86.5 km SSW Puerto Maldonado (13°08'53"S, 69°37'02"W). 30 November 1997. Tiffany M. Doan and Wilfredo Arizábal Arriaga. MHNUNSAAC PT 393. Found in leaf litter at night. Another individual was caught at the same locality on 31 August 1997, but escaped. First record for Perú. Previously recorded in the countries of Brazil, Guyana (Peters and Orejas-Miranda 1970) and Ecuador (Duellman 1990). Also listed as a "probable" species for Perú (Lamar 1997).

Oxybelis argenteus (Vine Snake). TAMBOPATA PROVINCE: Cusco Amazónico, 15 km ENE Puerto Maldonado (12°32'28"S, 69°03'36"W). April 1997. Arturo Cornejo Farfán. MHNUNSAAC PT 184; EcoAmazonía, 35.2 km ENE Puerto Maldonado (12°31'44"S, 68°55'58"W). 8 October 1997. Wilfredo Arizábal Arriaga. MHNUNSAAC PT 351. Found sleeping on branches of shrubs ca. 1 m above the ground. First records for Provincia Tambopata. Previously recorded from Estación Biológica de Cocha Cashu, Provincia Manu, Departamento de Madre de Dios, ca. 290 km to the WNW (Rodríguez and Cadle 1990).

Rhinobothryum lentiginosum (Amazon Ringed Snake). TAMBOPATA PROVINCE: EcoAmazonía: 35.2 km ENE Puerto Maldonado (12°31'44"S, 68°55'58"W). 23 January 1997. Wilfredo Arizábal Arriaga. MHNUNSAAC PT 102; Cusco Amazónico, 15 km ENE Puerto Maldonado (12°32'28"S, 69°03'36"W). 19 February 1997. Wilfredo Arizábal Arriaga. MHNUNSAAC PT 007. Found at night on the forest floor near small pools of water. First records for Provincia Tambopata. Previously recorded in Estación Biológica de Cocha Cashu, Provincia Manu, Departamento de Madre de Dios, ca. 290 km to the WNW (Rodríguez and Cadle 1990).

Acknowledgments.—We are grateful to Chris Kirkby, Huw Lloyd, Arturo Palomino Marín, Arturo Cornejo Farfán, and James I. Watling for our years of stimulating work together. We also thank all of our many assistants. Finally, we thank Victor Velásquez Zea for his assistance in

obtaining permits and his fight against the illegal pet trade.

This article represents a continuation of recent contributions focusing on new county records of amphibians and reptiles in Illinois. Recent articles published in *Herpetological Review* include Tucker (1994, Herpetol. Rev. 25:79–80), Redmer and Ballard (1995, Herpetol. Rev. 26:49–53), Petzing et al. (1998, Herpetol. Rev. 29:179–182) and Wilson (1999, Herpetol. Rev. 30:118–120). Specimens reported herein are housed in the Illinois Natural History Survey (INHS) and Southern Illinois University at Carbondale (SIUC) herpetological collections. County records were verified by checking the Illinois Herpetological Database, located at the Illinois Natural History Survey, which contains data on Illinois amphibians and reptiles from thirty museum and private collections and unvouchered records from herpetologists and other reliable biologists. Using information from the database, a web page was developed to provide county-level distribution data for amphibians and reptiles in Illinois. This web site can be accessed via the following URL:

http://www.inhs.uicc.edu/cbd/herpdist/herp.html

The database can be searched by either species or county. Distribution maps or county species lists may be printed out for field reference or other relevant uses.

CAUDATA

Ambystoma maculatum (Spotted Salamander). EDWARDS Co: 4.75 km N Albion; 0.9 km E Illinois Rt. 130 (SW 1/4 SE 1/4 Sec. 13, T1S, R10E; UTM Zone 16: N4253930m, E408660m). 28 February 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14034. New county record; WHITE Co: 2 km E Burnt Prairie and just N I-64 (NE 1/4 Sec. 20, T3S, R9E; UTM Zone 16: N4234440m, E392440m). 27 February 1998. J. E. Petzing and M. J. Dreslik. Verified by C. A. Phillips. INHS 14087. New county record. Metamorph.

Ambystoma opacum (Marbled Salamander). CLAY Co: 4.8 km NE Xenia (SW 1/4 Sec. 25, T3N, R5E). 2 May 1998. K. M. Weidner. Verified by C. A. Phillips. INHS 13952. New county record; EDWARDS Co: 4.75 km N Albion; 0.9 km E Illinois Rt. 130 (SW 1/4 SE 1/4 Sec. 13, T1S, R10E; UTM Zone 16: N4253930m, E408660m). 24 January 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14035. New county record.

Ambystoma texanum (Smallmouth Salamander). KNOX Co: 1.8 km WNW De Long (NW 1/4 SW 1/4 Sec. 30, T10N, R2E; Lat/Long: 40°49.283'N, 90°19.551'W). 27 May 1999. T. G. Anton and D. Mauger. Verified by C. A. Phillips. INHS 15005. New county record. Larva dipnetted from ditch.

Plethodon cinereus (Redback Salamander). COLES Co: 2 km N Hutton at Frank Hedges' farm (NE 1/4 NW 1/4 Sec. 3, T11N, R10E). 24 April 1989. F. Hedges. Verified by C. A. Phillips. INHS 14701. New county record; LAWRENCE Co: S side Indian Creek, Lawrenceville (NE 1/4 SW 1/4 Sec. 18, T3N, R11W). 1 May 1999. J. G. Palis. Verified by R. A. Brandon. SIUC H-5726. New county record. Ten specimens were collected in a rich, mesic hardwood forest on a north-facing slope. A total of 24 animals were observed, 22 of which were lead phase.

Plethodon glutinosus (Slimy Salamander). JASPER Co: Prairie Ridge State Natural Area (SW 1/4 Sec. 30, T6N, R9E). 30 April 1999. D. J. Olson. Verified by C. A. Phillips. INHS Herpetological Slide 1999-16. New county record. Specimen not collected because it was found on state protected land; LAWRENCE Co: S side Indian Creek, Lawrenceville (NE 1/4 SW 1/4 Sec. 18, T3N, R11W). 1 May 1999. J. G. Palis. Verified by R. A. Brandon. SIUC H-5727. New county record. Adult collected in rich, mesic hardwood forest on a north-facing slope; PERRY Co: 5.7 km SW Pinckneyville, Arch Minerals woodlot (NW 1/4 Sec. 4, T6S, R3W; UTM Zone 16: N4212430m, E285670m). 14 April 1998. J. E. Petzing and M. J. Dreslik. Verified by C. A. Phillips. INHS 13904. New county record.

Necturus maculosus (Common Mudpuppy). MCLEAN Co: Mackinaw River, E Gridley Blacktop Road bridge (NE 1/4 NW 1/4 Sec. 5, T25N, R3E). October 1998. R. C. Dobbs and D. B. Shepard. Verified by C. A. Phillips. INHS 14796. New county record.

Notophthalmus viridescens louisianensis (Central Newt). WILL Co: 0.8 km SE of Braidwood, Braidwood Dunes and Savanna Nature Preserve (SW 1/4 Sec. 16, T32N, R9E). 12 May 1991. D. O'Connell. Verified by C. A. Phillips. INHS 14700. New county record.

Siren intermedia (Western Lesser Siren). COLES Co: 4 km SE Charleston, backwater of Embarras River. 27 February 1986. E. O. Moll. Verified by C. A. Phillips. INHS 14702. New county record. Specimen found dead in ice.

ANURA

Bufo americanus (American Toad). MOULTRIE Co: 4 km WSW Allenville near Illinois Natural History Survey Kaskaskia Biological Station on Co. Rd. 1000N (NW 1/4 NW 1/4 NE 1/4 Sec. 30, T13N, R6E; UTM Zone 16: N4378750m, E364770m). 3 August 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14188. New county record; PERRY Co: 6.4 km SW Pinckneyville (SW 1/4 Sec. 4, T6S, R3W; UTM Zone 16: N4211705m, E285495m). 14 April 1998. J. E. Petzing and M. J. Dreslik. Verified by C. A. Phillips. INHS 13909. New county record.

Bufo fowleri (Fowler's Toad). EDWARDS Co: 4.5 km N Albion; 0.3 km E Illinois Rt. 130 (SW 1/4 SW 1/4 Sec. 13, T1S, R10E; UTM Zone 16: N4253810m, E408000m). 7 July 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14189. New county record; MOULTRIE Co: 4 km WSW Allenville near Illinois Natural History Survey Kaskaskia Biological Station on Co. Rd. 1000N (NW 1/4 NW 1/4 NE 1/4 Sec. 30, T13N, R6E; UTM Zone 16: N4378750m, E364770m). 17 July 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14186. New county record.

Acris crepitans (Northern Cricket Frog). MERCER Co: 5.75 km NNE Alexis, North Henderson Creek at Co. Rd. 2900E (SW 1/4 SW 1/4 NW 1/4 Sec. 17, T13N, R1W; UTM Zone 15: N4554320m, E707180m). 22 September 1998. J. E. Petzing and C. A. Phillips. Verified by M. J. Dreslik. INHS 14207. New county record; STARK Co: 1.25 km W Wyoming, Spoon River at Illinois Rt. 17/Illinois Rt. 91 (SE 1/4 Sec. 34, T13N, R6E; UTM Zone 16: N4549335m, E265095). 21 May 1998. J. E. Petzing. Verified by C. A. Phillips. INHS 13979. New county record.

Hyla chrysoscelis/Hyla versicolor (Gray Treefrog Complex). BUREAU Co: 12 km N Mineral, Fairfield Union Special Ditch at Co. Rd. 2400N (SW 1/4 Sec. 33, T18N, R6E; UTM Zone 16: N4597520m, E265140m). 15 July 1999. M. E. Retzer and T. J. Near. Verified by C. A. Phillips. INHS 15007. New county record; GALLATIN Co: 3 km NNE Old Shawneetown on Round Pond Road (NE 1/4 Sec. 20, T9S, R10E; UTM Zone 16: N4176160m, E401030m). 25 May 1998. M. J. Dreslik and A. R. Kuhns. Verified by C. A. Phillips. INHS 14006. New county record; MARSHALL Co: SE of jct. Illinois Rt. 26 and Atchison, Topeka and Santa Fe RR tracks (SW 1/4 NW 1/4 Sec. 35, T29N, R3W). 18 May 1999. A. R. Kuhns and D. B. Shepard. Verified by C. A. Phillips. INHS 14808. New county record; TAZEWELL Co: 3.2 km N Mackinaw on the Dee-Mac Road (NE 1/4 Sec. 6, T24N, R2W). 12 April 1998. R. J. Whitlatch. Verified by C. A. Phillips. INHS 13953. New county record; WHITESIDE Co: Sterling, lot bordered by E 9th Street to the N, E 8th Street to the W, E 7th Street to the S and 4th Avenue to the E (SE 1/4 Sec. 21, T21N, R7E; UTM Zone 16: N4630150m, E276200m). 12 August 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14187. New county record.

Pseudacris crucifer (Spring Peeper). MARSHALL Co: 0.6 km E Illinois Rt. 26 on Atchison, Topeka and Santa Fe RR (SE 1/4 NW 1/4 Sec. 35, T29N, R3W). 6 April 1999. D. B. Shepard and A. R.

Kuhns. Verified by C. A. Phillips. INHS 14797. New county record; SALINE CO: 0.8 km E Williamson-Saline Co. line and just N of new Illinois Rt. 13 alignment; 6.8 km NW Carrier Mills (SW 1/4 Sec. 18, T9S, R5E). 12 May 1999. J. E. Petzing. Verified by C. A. Phillips. INHS 15038. New county record. Series of five metamorphs. Collected as tadpoles and raised in the lab through metamorphosis; WOODFORD CO: NW Metamora, jct. Co. Rd. 825E and Co. Rd. 1650N (SW 1/4 NW 1/4 Sec. 6, T26N, R2W; UTM Zone 16). 6 April 1999. A. R. Kuhns and D. B. Shepard. Verified by C. A. Phillips. INHS 14802. New county record.

Pseudacris triseriata (Western Chorus Frog). EDWARDS CO: 4.6 km N Albion; 0.4 km E Illinois Rt. 130 (NW 1/4 Sec. 24, T1S, R10E; UTM Zone 16: N4253735m, E408170m). 20 March 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14032. New county record; MARSHALL CO: NE jct. Illinois Rt. 26 and Atchison, Topeka and Santa Fe RR tracks (SW 1/4 NW 1/4 Sec. 35, T29N, R3W). 18 May 1999. D. B. Shepard and A. R. Kuhns. Verified by C. A. Phillips. INHS 14806. New county record.

Rana blairi (Plains Leopard Frog). FAYETTE CO: 8.5 km SE Herrick, Kaskaskia River at Lorton Bridge (SW 1/4 Sec. 32, T9N, R3E; UTM Zone 16: N4338055m, E336370m). 12 July 1998. J. E. Petzing and J. W. Petzing. Verified by C. A. Phillips. INHS 14063. New county record; FORD CO: 4 km SW Paxton, Big Four Ditch at Co. Rd. 1600E (SE 1/4 SE 1/4 Sec. 15, T23N, R9E; UTM Zone 16: N4477570m, E401890m). 17 September 1999. J. E. Petzing and C. A. Phillips. Verified by M. J. Dreslik. INHS 15019. New county record; MERCER CO: 4.75 km NNE Alexis, North Henderson Creek at Co. Rd. 2835E (SW 1/4 SE 1/4 Sec. 18, T13N, R1W; UTM Zone 15: N4553700m, E706400m). 22 September 1998. C. A. Phillips and J. E. Petzing. Verified by M. J. Dreslik. INHS 14210. New county record.

Rana catesbeiana (Bullfrog). BUREAU CO: 2.8 km W La Moille, Big Bureau Creek at Co. Rd. 2600N (SE 1/4 SE 1/4 SW 1/4 Sec. 22, T18N, R10E; UTM Zone 16: N4599400m, E306000m). 20 August 1998. J. D. Evans and L. M. Page. Verified by C. A. Phillips. INHS 14185. New county record; CARROLL CO: 5.5 km NNW Savanna, slough along the Mississippi River; 0.4 km NW Mississippi Palisades State Park office (SE 1/4 SE 1/4 Sec. 20, T25N, R3E). 1 April 1999. C. D. Smith. Verified by C. A. Phillips. INHS 15046. New county record; CRAWFORD CO: 2 km SSE West York at Raccoon Creek (SW 1/4 Sec. 8, T8N, R11W). 17 May 1999. L. M. Page, M. Hardman, S. Herrington and J. D. Evans. Verified by C. A. Phillips. INHS 15075. New county record; DOUGLAS CO: 2.9 km W Camargo at Spring Lake (NE 1/4 SW 1/4 Sec. 33, T16N, R9E; UTM Zone 16: N4405600m, E397900m). 13 September 1999. C. A. Phillips. Verified by J. E. Petzing. INHS 15065. New county record.

Lampropeltis getula nigra (Black Kingsnake). GALLATIN CO: 1 km E Ridgway, jct. Ridgway-New Haven Road (Co. Rd. 15500N) and Farmer Rd. (Co. Rd. 7500E) on Ridgway-New Haven Road (Center Sec. 29, T8S, R9E; UTM Zone 16: N4184030m, E390960m). 25 June 1999. J. E. Petzing and M. J. Dreslik. Verified by C. A. Phillips. INHS 14793. New county record. DOR.

Nerodia erythrogaster (Plainbelly Water Snake). CLAY CO: Ditch on E side of Co. Rd. 2075E (AKA Co. Rd. 2100E), 20 m S Co. Rd. 800N (E of Flag Pond) (NW 1/4, NW 1/4, NW 1/4, NW 1/4 Sec. 10, T3N, R8E). 9 May 1999. J. G. Palis. Verified by R. A. Brandon. SIUC R-3164. New county record. Neonate; LAWRENCE CO: N Lawrenceville; Illinois Rt. 1, 1.3 km N U. S. Rt. 50 (NW 1/4 SW 1/4 Sec. 30, T4N, R11W). 1 May 1999. J. G. Palis. Verified by R. A. Brandon. SIUC R-3165. New county record. DOR adult.

Nerodia rhombifer (Diamondback Water Snake). JEFFERSON CO: 4.6 km W Mt. Vernon; 0.2 km E Big Muddy River on Illinois Rt. 15 (SW 1/4 NE 1/4 Sec. 33, T2S, R2E; UTM Zone 16: N4241830m, E326370m). 6 May 1999. J. E. Petzing and M. J. Dreslik. Verified by C. A. Phillips. INHS 14686. New county record. DOR juvenile; MARSHALL CO: 0.2 km S jct. Illinois Rt. 26 and Atchison, Topeka and Santa Fe RR (SW 1/4 NW 1/4 Sec. 35, T29N, R3W). 18 July 1999. D. B. Shepard. Verified by C. A. Phillips. INHS 14851. New county record. Juvenile.

Nerodia sipedon (Northern Water Snake). CLAY CO: 6.75 km SE Clay City, Little Wabash River at Co. Rd. 250N (Wilcox Bridge) (Sec. 3, T2N, R8E; UTM Zone 16: N4277000m, E387093m). 8 September 1998. C. A. Phillips, K. S. Cummings and W. C. Handel. Verified by J. E. Petzing. INHS 14178. New county record. Collected near the county line; Ditch on W side of Co. Rd. 2075E (aka Co. Rd. 2100E), 1.3 km N U. S. Rt. 50 (NE 1/4 Sec. 16, T3N, R8E). 9 May 1999. J. G. Palis. Verified by R. A. Brandon. SIUC R-3162. This record included because the locality is further within the county than the previous record; EDWARDS CO: 5.4 km N Albion, N side Moose Lake (NE 1/4 Sec. 14, T2S, R10E; UTM Zone 16: N4254550m, E407430m). 12 April 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14029. New county record; MOULTRIE CO: 4 km WSW Allenville near Illinois Natural History Survey Kaskaskia Biological Station (NW 1/4 NW 1/4 NE 1/4 Sec. 30, T13N, R6E; UTM Zone 16: N4378750m, E364770m). 8 September 1998. C. D. Smith. Verified by C. A. Phillips. INHS 14194. New county record.

Regina septemvittata (Queen Snake). MARSHALL CO: 0.6 km S Co. Rd. 115N on Illinois Rt. 26 (NE 1/4 NE 1/4 Sec. 34, T29N, R3W; UTM Zone 16: N4534070m, E295490m). 27 June 1999. D. B. Shepard. Verified by C. A. Phillips. INHS 14812. New county record. DOR adult.

Storeria dekayi (Brown Snake). PERRY CO: 5.7 km SW Pinckneyville, Co. Rd. 800E (NW 1/4 Sec. 4, T6S, R3W; UTM Zone 16: N4212470m, E285410m). 1 June 1999. J. E. Petzing and M. J. Dreslik. Verified by C. A. Phillips. INHS 14757. New county record. DOR juvenile.

Thamnophis radix (Plains Garter Snake). WHITESIDE CO: 1.26 km E Morrison on Bishop Rd. (SW 1/4 NW 1/4 Sec. 16, T21N, R5E). 13 April 1999. C. D. Smith. Verified by C. A. Phillips. INHS 15051. New county record. DOR.

Thamnophis sirtalis (Common Garter Snake). LAWRENCE CO: Lawrenceville, 15 m E former RR grade (W 1/2 NW 1/4 Sec. 18, T3N, R11W). 2 May 1999. J. G. Palis. Verified by R. A. Brandon. SIUC R-3166. New county record. Adult collected under trash; WHITE CO: U. S. Rt. 45, 4.2 km N Illinois Rt. 141 (Gallatin Co. line) (E 1/2 Sec. 5, T7S, R8E). 8 September 1998. J. G. Palis. Verified by R. A. Brandon. SIUC R-3438. New county record. DOR adult.

Crotalus horridus (Timber Rattlesnake). COLES CO: just E of Charleston. September 1917. Verified by C. A. Phillips. INHS 13857. New county record. Formerly in the Eastern Illinois University Teaching Collection.

Acknowledgments.—We would like to thank Fredric J. Janzen for permission to publish the Carroll County *Graptemys geographica* record and Kevin S. Cummings and Christopher A. Taylor for reviewing the manuscript. Field work by JEP, MJD and CAP was partially supported by a contract with the Illinois Department of Transportation and grants from the Wildlife Preservation Fund (Illinois Department of Natural Resources, Division of Natural Heritage) to JEP, and a grant from the Wildlife Preservation Fund, Illinois Endangered Species Protection Board, and the Linnaeus Fund of the Chelonian Research Foundation to MJD. Field work by JGP was partially funded by a grant awarded to BK from the U.S. Office of Surface Mining Regulation and Enforcement. JGP would like to thank Ronald Brandon and Karen Lips for expediting the process of assigning museum numbers to his specimens. Field work by DJO was partially funded by a grant from the Wildlife Preservation Fund (Illinois Department of Natural Resources, Division of Natural Heritage). DJO would also like to thank Scott Simpson (Prairie Ridge State Natural Area Supervisor), Terry Esker (IDNR District Heritage Biologist), Eric Kershner, and Jeff Walk.

While conducting herpetological investigations for the Mendocino and Plumas National Forests, five new county records for two amphibian and two reptile species were noted from Colusa, Glenn, Plumas, and Yuba counties, California, from within the boundaries of the national forests.

Localities for these specimens were compared with the following references: Cook (1960), Nussbaum (1976), and Wake and Yanev (1986). Localities were also compared with records from the following institutions: AMNH, BYU, CAS, Chico State University, CM, FMNH, HSU, KU, LACM, MCZ, MVZ, OS, SDSNH, SSU, TNHC, UMMZ, University of Nevada (Las Vegas), UNR, USNM, and UTA (museum codes follow Leviton et al. 1985). All identifications were verified by R. C. Drewes.

Dicamptodon tenebrosus (Pacific Giant Salamander). COLUSA CO: Mendocino National Forest, unnamed tributary to the South Fork of Stony Creek at Davis Flat, SE 1/4 Sec. 32, T17N, R7W. 9 March 1991. M. R. Jennings and M. P. Hayes. CAS 180325. This is the first record of *Dicamptodon* from Colusa County, and we tentatively identify the specimen as *D. tenebrosus*. Nussbaum (1976) recognized morphological differences between populations of *D. ensatus* from south of Mendocino, Lake, and Glenn counties and the more northern populations. He found the southern populations had larger heads, higher numbers of maxillary, premaxillary, and vomerine teeth, and lack palatopterygoid teeth in the larvae. Nussbaum hypothesized that the "North Coast Divide" (from coastal southern Mendocino County east to southern Lake County and north to Glenn County) may provide a dispersal barrier. From allozyme variation, Good (1989) suggested that two cryptic species of *Dicamptodon* occur in northern California, with the contact zone occurring in southern Mendocino County. However, the contact zone was only analyzed for coastal populations, leaving the status of inland populations in question. Good (1989) mentioned that preliminary analysis of inland populations did not correspond to Nussbaum's "North Coast Divide," but he did not give any indication of the area of contact between the inland forms. Although Nussbaum included specimens from southern Glenn County in the southern form, we found this specimen from Colusa County (south of Glenn County) to have the characteristics of Nussbaum's northern populations, including the presence of palatopterygoid teeth.

The specimen was found in a creek draining the eastern slope of the North Coast Range in dry habitat dominated by mixed chaparral and Gray Pine (*Pinus sabiniana*).

Ensatina eschscholtzii (Ensatina). COLUSA CO: Mendocino National Forest, Dixie Glade Campground (39°20'09.5"N, 122°42'09.8"W), ca. 918 m elev. Under log. 29 March 1997. J. V. Vindum. CAS 202596; Mendocino National Forest, Forest Rd M10, 17.6 km W (by road) of Stonyford, N slope of Potato Hill, (39°20'40.0"N, 122°41'01.1"W), 841 m elev. N facing slope, under rocks. 18 January 1997. J. V. Vindum. CAS 202444-45; Mendocino National Forest, Forest Rd M10, 18.56 km W (by road) of Stonyford, N slope of Potato Hill, (39°20'31.5"N, 122°41'41.4"W), 866 m elev. N facing slope, under rocks and wood. 19 January 1997. J. V. Vindum. CAS 202451; PLUMAS CO: Plumas National Forest, French Creek, NE 1/4 of SW 1/4 Sec. 23, T26N, R7E (40°05'33.0"N, 121°09'49.33"W), 1244 m elev. In log next to stream. 24 August 1999. J. A. Wilkinson and J. V. Vindum. CAS 209431.

Contia tenuis (Sharptail Snake). GLENN CO: Mendocino National Forest, Brittan Ranch (39°23'20.6"N, 122°39'42.0"W), 708 m elev. 24 February 1997. J. V. Vindum. CAS 202582; Mendocino National Forest, Brittan Ranch (39°23'34.9"N, 122°39'41.0"W), 708 masl. 24 February 1997. J. V. Vindum. CAS 202585.

Crotalus viridis (Western Rattlesnake). YUBA CO: Plumas National Forest, Scales Road (Forest Road 04), ca. 1.1 km S (by road) of Quincy La Porte Hwy, NW 1/4 of SW 1/4 Sec. 22, T20N, R8E (39°34'39.6"N, 121°04'31.18"W), 1242 m elev. Alive on road. 9 August 1999. R. S. Lucas and K. D. Wiseman. CAS 209705.

Acknowledgments.—We thank Linda Tatum, Mendocino National Forest, and Cindy Roberts, Plumas National Forest. Funding for field work was made possible by a Challenge Cost-Share Agreement between CAS and the U.S. Department of Agriculture, Forest Service, Mendocino National Forest (CCS-5-99-08-017) and Plumas National Forest (CCS-5-99-20-069), and generous donations to the Department of Herpetology, CAS, from Emily Date, Malcolm Miller, and the late Richard Dumke.

The Amphibians of Java and Bali, by Djoko T. Iskander. 1998. Research and Development Centre for Biology - LIPI Indonesia. xix + 117 pp. Softcover. US $25.00. ISBN 979-579-014-5.

MICHAEL J. TYLER
Department of Environmental Biology, University of Adelaide
SA 5005, Australia
e-mail: michael.tyler@adelaide.edu.au

As Bob Inger points out in the Preface, there has been no synthesis of the amphibians of Java and Bali since Van Kampen produced *The Amphibia of the Indo-Australian Archipelago* in 1923. It follows that this book by Djoko Iskander is a most welcome one, and a significant step in the documentation of the herpetofauna of the many major islands that comprise Indonesia.

The contents are presented in an orderly fashion with separate chapters on biology, classification, identification to families and identification of tadpoles, followed by species accounts of the single caecilian (*Ichthyophis hypocyaneus*) and 40 species of frogs grouped in seven families. Of those species three are introduced : *Rana catesbeiana*, *Xenopus laevis* and *Hymenochirus* sp. Given the known establishment of *Litoria infrafrenata* at Bogor, and the report by Iskander that *Ceratophrys* has been seen in Javanese pet shops, the proportion of exotic species in Java is substantial and the risk to the native species from colonizers is high.

The species accounts are concise but detailed with separate sections on etymology, type locality, description, size, skin texture, color, reproduction, habitat, chromosome number, known localities (supported by details of the museum catalogue numbers of the specimens on which those records are based), distribution outside Java, other known names, and related species.

The text contains numerous interesting facts that will appeal to the historian, such as that Kuhl and Van Hasselt (authors of *Megophrys* and *Rhacophorus*) died at the ages of 24 and 26, respectively, and share a tomb in the Bogor Botanical Gardens. There are fascinating notes on defense mechanisms and reference to a curious skin exudate of *Kalophrynus*: "If you held such a frog... firmly in your palm, it will be very difficult to open your fist again" (p. 6).

As is to be expected in any work of this kind, some of the nomenclatural actions will be debated. For example, the recognition of the Pelodryadidae and, particularly, the inclusion of *Hyla javana* Ahl as a *Litoria* species. Like *Rhacophorus depressus* Ahl, which Iskander excludes, this species is almost certainly based upon a specimen taken elsewhere in the world, and it should have been treated in a similar fashion.

Rarely have I enjoyed so much browsing through a field guide and I commend it highly. My only word of caution is to those attracted by the caption to the "shingle stream" in Plate 1 as "an ideal habitat for amphibians at night." Within my experience, the raging torrent and precipitous boulders indicate that it is not an ideal habitat for collectors at night.

e-mail: rdesa@richmond.edu

This book focuses on the batrachofauna of Barro Colorado Nature Monument, Soberania National Park and adjacent areas. It complements other recent publications on Neotropical amphibians such as those by Rodríguez and Duellman (1994) on Peru, Achaval and Olmos (1995) on Uruguay, and Meyer and Foster (1996) on Belize. The goal of these books is to reach a wider audience than the more technical batrachofaunal summaries—e.g., *Frogs of Boracéia* (Heyer 1990), *Amphibians of Argentina* (Cei 1985), and *Frogs of the Genus Eleutherodactylus* in Western Ecuador (Lynch and Duellman 1997). These geographically focused guides are especially useful to students, amateur biologists, and to the increasingly omnipresent ecotourists roaming the Neotropics. However, they are also valuable tools for beginning biology graduate students who are looking for an "organism" to work on, as well as to the trained herpetologist visiting an area for the first time.

A distinctive and positive feature of this book is its completely bilingual format. This format is targeted toward students and professionals in Latin America and undoubtedly it will be well received there.

The authors provide an informative map of the region with key localities clearly identified and plotted. Good quality photographs are provided for each of the 62 amphibian species occurring in the area. In addition, sonograms are presented for 52 out of the 59 frog species considered.

Each of the species accounts includes an overall description of adults, with a few diagnostic characteristics noted in italics for quick identification, followed by brief descriptions of the calls

and notes on the natural history of the species. A CD complements the descriptions of calls. The sonograms will be of interest to the technical reader, whereas the actual CD sounds would help individuals in the field. The natural history notes include a bit of ecology of calling males and site of egg deposition. Parental care information and the presence of a free-swimming tadpole stage are noted where appropriate. The final component in each species account is a brief summary of key references. These references will point interested individuals toward information for additional studies and details on the biology of each species.

Incorporating tadpole illustrations and descriptions with the species accounts could have strengthened this book. These geographic guides tend to overlook the characteristics of the larval stage, missing the opportunity to produce complete summaries of the biology of the amphibians inhabiting any area. The second, and more important, shortfall is the absence of dichotomous keys for genera and species identification. The inclusion of such keys would have been extremely beneficial for all who would use this book, particularly while visiting the Barro Colorado area. Nonetheless, the authors have done a good job summarizing information for the amphibians of Barro Colorado and this guide will be of widespread use and interest to anyone visiting or working in Barro Colorado and surrounding areas.

The Lizards of Iran, by Steven C. Anderson. 1999. Society for the Study of Amphibians and Reptiles, Oxford, Ohio. vii + 442 pp, 25 plates. Hard cover. US $65.00. ISBN 0-916984-49-4.

NASRULLAH RASTEGAR-POUYANI
Department of Biology, Faculty of Science, Razi University
Kermanshah, Iran

Herpetologically and biogeographically, Iran is one of the most complex countries in the Middle East and Southwest Asia. It serves as a crossroad between North Africa, Arabia, Central Asia, southeastern Europe and the Oriental region (southern Pakistan and northwest India). Iran covers an area of 1,648,000 km^2, situated between latitudes 25° and 39°N and longitudes 44° and 62°E (Davoudzadeh 1997). This large territory is very rich from the standpoint of its lizard fauna; to date 122–125 lizard taxa belonging to 34 genera and 8 families have been documented, and additional taxa may be expected from the remote and poorly investigated regions of the country.

For nearly half a century Steven Anderson has studied the lizard fauna of the Iranian Plateau and has made pioneering contributions to our knowledge of the saurology of the region (Rastegar-Pouyani 1999a). During extended field trips in 1958 and 1975 Anderson conducted field work in most parts of Iran, including the harsh lowland southwest of the country. He has observed most of the lizard species of the region and has published extensively on them (e.g., Anderson 1963, 1966a,b,c, 1968, 1974). Now, and after more than forty years of study and research, he has produced *The Lizards of Iran* as a definitive work based on museum material from collections throughout the world, an extensive review of relevant literature, and his own considerable field and laboratory experience.

The Lizards of Iran is nearly 450 pages long and is illustrated by 25 plates (including two black and white satellite photographs of Iran, 150 color photos of lizards [plates 1–19], and 38 color photos of their habitats [plates 20–25]), as well as 137 figures in the text. Furthermore, some 32 figures, mainly illustrating the identification keys, and 109 distribution maps are distributed throughout the text. The book represents an ambitious, well-written, and successful attempt to summarize almost all that is known about the lizards of Iran. As the first handbook on Iranian lizards it will undoubtedly serve as an invaluable reference for herpetologists carrying out further regional research.

The book is organized into two main parts: a general section (pp. 9–65) and a systematics section (pp. 66–299). A prelude by Eskandar Firouz (a former deputy to the prime minister of Iran and director, Department of Environment) precedes the introduction. The general, introductory part of the book is subdivided into several subheadings: an introduction, in which the author gives a short account of his two field trips in Iran in 1958 and 1975; a short, but impressive, history of herpetological investigations in the Iranian Plateau including a review of key workers and their publications, and an overview of biogeography and ecology of the lizards of Iran (pp. 42–65) which provides an excellent data-rich summary of these topics. Here, all the different physiographic regions and main drainages of Iran are succinctly reviewed and the composition of their lizard faunas are given, with emphasis on the endemic species. The role of physical and biological factors affecting lizard distribution and abundance (e.g., substrate type, temperature, moisture, vegetation, predation) is also discussed. Relationships of the Iranian Plateau lizard fauna to that of adjacent areas are documented, the number of taxa shared with each region is given, and the role of paleogeographic events (e.g., plate tectonics) on the evolution and present distribution of the lizard fauna of Iran is discussed.

Regarding this general part of the book, a few errors need to be mentioned: in one instance, at least, the names Zagros and Albors have been confused (p. 50); on page 58, the Masjid-e-Soleyman region in southwestern Iran is illustrated in plate 22A–C (rather than 21A–C); it does not appear that *Laudakia nupta, Trapelus ruderatus* (now *Trapelus lessonae*), *Eublepharis angramainyu, Asaccus griseonotus, Carinatogecko heteropholis, Cyrtopodion*

heterocercum, Lacerta cappadocica, L. media, and *L. princeps* occur in Kuwait (p. 60) unless we regard Iraq and Kuwait as a single entity!; *Laudakia microlepis* should be included to the list of the fauna of Pakistan and Afghanistan (p. 61); and the occurrence of *Ophisops elegans* in Turkmenistan (p. 61) is highly doubtful and contradicts the information in the species account for this taxon.

The systematic section, as the core of the book, covers the lizard fauna of the entire territory of Iran, which includes 8 families, 34 genera, and some 123 species (21 agamids, 2 anguids, 3 eublepharids, 40 gekkonids, 38 lacertids, 14 scincids, 3 uromasticids, and 2 varanids). It begins with a key to the lizard families of Iran, followed by family, generic, and species accounts in alphabetical order. A brief overview is provided for each family (except Varanidae) followed by a key to the relevant genera occurring in Iran. Each genus is treated under the subheadings "definition," "distribution," and "remarks." In the diagnosis of species and subspecies, external morphological characters (mostly scalation and color pattern) are employed almost exclusively, but for the definition of families and sometimes genera, osteological characters are frequently used. Keys are provided for all the species and subspecies (both documented and doubtful taxa). To the best of my knowledge, most keys are workable and clear.

Species accounts constitute the main part of the systematics section, covering all 123 (110 documented and 13 doubtful) lizard species. Descriptions are based on the author's own observations and field work as well as the literature. Each account provides almost all available relevant data. Information concerning the extralimital taxa are provided only if the data are lacking for the Iranian ones. Species accounts are relatively comprehensive, consisting of the name of the original describer, type(s) and type locality, a list of synonyms (if any) as well as scientific and English vernacular names, diagnosis, color pattern, size, habitat, distribution, and remarks. Accounts vary in their thoroughness depending in part on whether the information was derived chiefly from field study by the author, museum collections, or the literature. Individual accounts range from about half a page (e.g., *Carinatogecko heteropholois, Acanthodactylus nilsoni, Ophiomorus persicus*) to about five pages (*Trapelus agilis*).

Distribution spot maps for all taxa occurring in Iran are provided (except for *Lacerta media media*). The distribution of each taxon (species or subspecies) is shown as a series of solid or open symbols, the former identifying specimens examined by the author, the latter those reflecting literature records. These symbols are plotted onto a small, simple map of Iran without further information. The type localities, if applicable, are represented as rectangles. Most species as well as some relevant habitats are represented by high quality photographs grouped into a series of plates at the end of the systematic section. Further, line drawings or black and white photos frequently accompany the description of species in the text. The text figures are mainly taken from older literature sources and are, in some cases, of poor quality.

Different systems of classification are followed throughout the book including both traditional and modern approaches. For instance, the taxonomy of the Gekkota mostly follows Kluge (1987) and Grismer (1988), recognizing the Eublepharidae as a familially distinct monophyletic group, with all other Iranian taxa belonging to the family Gekkonidae (Kluge 1967, 1983, 1985; Szczerbak and Golubev 1986). The problematic inter- and intrageneric relationships of the arid Asian gekkonids (e.g., *Agamura, Bunopus, Carinatogecko, Cyrtopodion*) remain unresolved. In the taxonomy of the Agamidae, the author has followed the unpublished thesis of Moody (1980), separating *Uromastyx* from the other Iranian genera of agamids, placing it, along with the Southeast Asian *Leiolepis*, in the family Uromastycidae (although this grouping has subsequently been regarded by some authors as a subfamily within the Agamidae; Barsuk-Bialynicka and Moody 1984). The systematic status of *Trapelus agilis,* and the traditionally recognized *T. persicus* and *T. ruderatus* complexes, are not clarified and, although the nomenclature of this group has changed greatly in recent years, the book employs an older set of terminology. For example, *Trapelus agilis* now has four recognized subspecies, and the following names now refer to different biological entities than they did in the past: *T. ruderatus* (= the former *T. persicus*), *T. lessonae* (= the former *T. r. ruderatus*), and *T. megalonyx* (= the former *T. megalonyx* + *T. r. baluchianus*) (Rastegar-Pouyani 1998, 1999a,b,c, in press, unpubl. data). Further, it is not obvious whether Anderson accepts *Laudakia caucasia triannulata* as a distinct taxonomic entity. The validity of this trinomen has been rejected based on molecular as well as morphological studies (Macey et al. 1998; Rastegar-Pouyani and Nilson, unpubl. data).

The two main drawbacks of the book are the poor quality of some of the illustrations in the text and the complete lack of convenient, tabulated data in the main text. Most other problems reflect apparently inadvertent omissions and minor errors. Anderson claims (p. 100) that the holotypes of *Agama kirmanensis* and *A. kirmanensis* var. *brevicauda* are destroyed. However, I examined both of them in February 1996 during my visit to the Russian Academy of Sciences, St. Petersburg. The lack of a distribution map for *Lacerta media media* is surprising, as it is one of the best known lacertids in western and northwestern Iran. The distribution map of *Lacerta princeps princeps* and *L. p. kurdistanica* (p. 241) is problematic, being contradictory with the description in the text. It does not appear that the nominal subspecies (*L. p. princeps*) occurs in Kermanshah province. If it does occur there, then the relegation of these forms to subspecific status must be reconsidered. There are some minor misspellings of Persian terms throughout the book; however, as a native Persian (Farsi) speaker, I deeply appreciate the tremendous effort made by the author in translation and application of the Persian names.

Nearly one third of the book is devoted to literature citations, appendices, and an index. An impressive, accurate, and detailed bibliography (pp. 301–345), consisting of 929 references from 1758 to 1999, is one of the strongest points of *The Lizards of Iran.* It serves as a valuable resource for any aspect of the herpetology of the Iranian Plateau. Abbreviations for museums and author names are provided in Appendix I (pp. 347–349). All the material examined and their relevant Iranian localities in different Provinces (Ostans) are represented, in alphabetical order, in Appendix II (pp. 351–382). Here, the arrangement is based on Taxon / Province (Ostan). Appendix III (pp. 383–415) is a gazetteer providing almost all the Iranian reference localities (from the herpetological point of view) along with their relevant Province (Ostan) names. If available, latitude, longitude, and elevation are also given. In the second page of the gazetteer (p. 384) some Persian (Farsi) terms along with their correspondent English names are presented; unfortunately some of these have been inappropriately translated

(e.g., ab = water [not stream or well]; shekasteh = broken [not mountain]; jebal = mountains [not hills], shur = salty [not stream], etc.). An index to the authors, subjects, English and scientific names of the taxa (pp. 417–442) completes Anderson's book.

In short, *The Lizards of Iran* is an invaluable reference and a substantial contribution to the herpetology of a taxonomically and biogeographically key region. It represents the results of nearly half a century of study and research by the author in the field and laboratory. Steven Anderson deserves to be commended for producing such an important contribution to the knowledge of the herpetology of the Iranian Plateau. His book certainly serves as a standard for future regional monographic works, provoking constructive thoughts and encouraging further investigations of the lizard fauna of this herpetologically complex region. The book is for anyone interested in the saurology of the Iranian Plateau, Central Asia, or the Middle East. I strongly recommend that both professionals and amateurs add this important publication to their libraries.

Field Guide to Amphibians and Reptiles of Illinois, by Christopher A. Phillips, Ronald A. Brandon, and Edward O. Moll. 1999. Illinois Natural History Survey Manual (8):xiii–xv + 282 pp., Champaign, Illinois. ISBN 1-882932-04-8 . Cloth. US $19.95.

HARLAN D. WALLEY
Department of Biology, Northern Illinois University
Dekalb, Illinois 60115, USA
e-mail: hdw@niu.edu

Not since Philip W. Smith published his monographic study in 1961 has a major work on the herpetofauna of Illinois appeared. The Smith monograph was the first state monograph to use both excellent illustrations and distribution maps, along with complete ecological, distributional, and historical information, and has served as a guideline for subsequent state monographs.

The present volume is the eighth publication in a general series on the flora and fauna of Illinois. Previous volumes covered Illinois wildflowers, shrubs, land snails, mammals, mussels, and long-horned beetles. Each volume in this series has been compacted into a pocket guide, which can easily be carried in the field.

Like the preceding volumes, this small book is an excellent practical guide for the general public to aid in the identification of the 102 species of amphibians and reptiles that live within the boundaries of Illinois. It is organized in a manner that makes it easy to use for one with little or no prior knowledge. Basic information is presented on the biology and life history of amphibians and reptiles, and a brief account is given of the species that are listed under the State's Endangered Species Protection Act. This is followed by a short discussion on regulations for collecting and keeping herptiles, along with remarks on mortality and habitat improvement. There is also a short section on the "Geologic and Climatic History of Illinois," in which the authors discuss how earth history has played an important role in the former distribution and abundance of species within the state (although this has changed drastically due to human activities). This is followed by a glossary of terms, and an illustrated key to amphibians and reptiles of Illinois, using only common names.

After the key, individual accounts cover the 102 species within the state. The accounts are condensed, containing brief sections on identification, similar species, subspecies recognized within the state, short description, habitat, natural history notes, and status. The serious reader might have desired additional information in these accounts but what is presented is concise and accurate, and well suited to the function of the book as a field guide.

Each species account is provided with an excellent color photograph (the majority of which were taken by Mike Redmer), along with a color distribution map, which shows the counties cited with voucher specimens, photographic records, verified sightings, and pre-1980 records.

The individual species accounts are followed by a short section discussing species of questionable occurrence in Illinois (*Ambystoma tremblayi, Terrapene carolina triunguis*, and *Cemophora coccinea*). A short section on additional literature is followed by an index to common and scientific names which completes the volume.

I noted no errors in the text, except that on pages 15–16 one sentence has been duplicated. This is an excellent book that admirably fulfills its purpose. The authors should be commended for their effort. I recommend this publication to both laymen and professionals.

UNIVERSITY PRESS OF *Florida*

The Iguanid Lizards of Cuba

Lourdes Rodriguez Schettino, ed.

"Goes far beyond a standard taxonomic handbook or catalogue treatment covering not only information on systematics, morphology, ecology, and biogeography, but also behavior, parasitology, and genetics. . . . A tremendous resource and reference." —Kevin de Queiroz, National Museum of Natural History, Smithsonian Institution

Lourdes Rodriguez Schettino covers nearly every aspect of the 62 currently known iguanid species living in Cuba, including the iguana, the curly-tailed lizards, giant anoles, chameleons, and other anoline lizards. Her book contains distribution maps for every species and original, full-color illustrations for 57 species. She also treats current problems of conservation and biodiversity resulting from urban development. Cloth, $85.00

A Field Guide to the

Amphibians and Reptiles of the Maya World

The Lowlands of Mexico, Northern Guatemala, and Belize

JULIAN C. LEE

The Yucatán Peninsula is today divided among Belize, Guatemala, and Mexico. Travelers to this region discover both astonishing archaeological sites and a stunning array of wildlife, including crocodiles, turtles, lizards, snakes, frogs, toads, and salamanders. This book—written by the world's leading authority on the herpetology of the lowland Maya area—is the only comprehensive field guide to all the species of amphibians and reptiles found there.

A Comstock Book
163 maps, 25 photos, 174 line drawings,
191 color illustrations
$59.95 cloth, $35.00 paper

Dorsal view of Loggerhead Turtle hatching (*Caretta caretta*), drawing by Julian C. Lee.

Cornell University Press
At bookstores, or call (607) 277-2211 • www.cornellpress.cornell.edu

THIS FIELD GUIDE:

- **Allows identification of all native and introduced species of amphibians and reptiles of the region.**
- **Features nearly 180 color photographs and 180 drawings.**
- **Offers valuable techniques for field identification, and a glossary of herpetological terms.**
- **Provides in each species account: description, natural history, similar species, and geographic distribution (complete with maps of each animal's range).**
- **Includes suggested readings for those who want to know more about a particular species.**
- **Illustrates all tadpoles.**
- **Describes the most characteristic vocalizations of the reptiles and amphibians in the volume.**
- **Introduces the physical geography, climate, and vegetation of the region, with emphasis on the habitats of amphibians and reptiles.**

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA.

All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700		$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 700	$270

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@slu.edu.

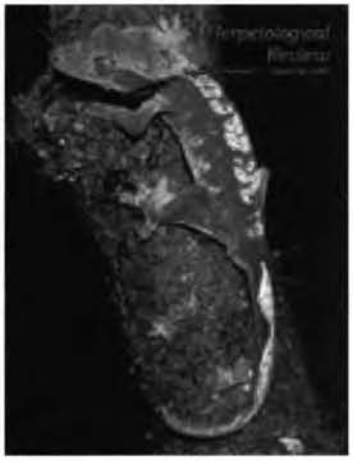
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.



ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2000 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@slu.edu.

Future Annual Meetings

2001 — Indiana University/Purdue University, Indianapolis, Indiana, USA, 26–30 July 2001

About Our Cover: *Rhacodactylus ciliatus*

Islands are fertile ground for the birth of species, thanks to their unique and complex mix of circumstances including isolation, small gene pools, and a limited number of predators. Reptiles endemic to islands sometimes evolve highly derived characteristics that would not normally be viable on a continental ecosystem. Gigantism is a case in point. Many reptile families can count island taxa among their largest extant members.

The French territory of New Caledonia is home to the richest herpetofauna of any non-archipelagic island group in the Pacific. It also harbors more endemic taxa, both in absolute numbers and as a percentage of its whole, than any other island in the Pacific except New Guinea (Bauer and Sadlier 1994. Pacific Science 48[4]:353–366). Among its suite of herpetological oddities are some of the world's largest geckos.

Giant geckos of the genus *Rhacodactylus* are endemic to New Caledonia. Six species are known to occur in the island's rainforests and *marquis*, the peculiar heath-like vegetation communities that thrive on the toxic, nickel-rich soils. The largest of these, with a snout-vent length of 245 mm or more, is *R. leachianus*, considered to be the world's largest living gekkonid. This great flabby gecko with its long, horse-like face and loose folds of skin is relatively common in humid forests throughout New Caledonia.

But perhaps the most enigmatic and spectacular is the crested gecko (*R. ciliatus*). This extraordinary lizard, with a snout-vent length of 'only' 130 mm, has an elaborate pair of spinose crests sweeping back from above each eye to form a parallel series on the nape. It also has extensive webbing at the rear of the hind limbs and a thin, cylindrical tail with a flattened, spatulate tip bearing adhesive lamellae.

Rhacodactylus ciliatus was described as *Correlophus ciliatus* by Guichenot in 1866. The type locality, given as simply *Nouvelle-Calédonie*, sheds no light on its provinence. A series of some 20 specimens collected in the latter part of the 1900's are labelled Ciu and Noumea but the latter is more likely a point of shipment than a collecting site for specimens (Bauer 1990. Bonn. Zool. Monogr. 30:1–220). No more were found for nearly a century and it was feared the lizard may have become extinct. In 1994 *Rhacodactylus ciliatus* was rediscovered on Ile des Pins (Isle of Pines), a small island about 50 kilometres off the southern tip of New Caledonia. Recently, more intensive field work has revealed crested geckos in at least three separate sites on the southern New Caledonian mainland.

Little has been documented on the crested gecko in the field. Bavay (1869. Mem. Soc. Linn. Normandie 15:1–37) considered it an inhabitant of montane forests that was seen only after rain, but field observations over the past several years revealed that it also occurs in warm, moist lowland forests. Fecal examinations reveal fruit to be a significant part of its diet although, not surprisingly, captive individuals thrive on a variety of insects. Original tails are uncommon on adults and they are said to be incapable of growing a new one, regenerating little more than a stump.

The large adult pictured, complete with original tail, was one of three specimens including two juveniles that were found foraging on saplings and tree limbs in dense forest in southern New Caledonia. In keeping with Bavay's observations of 130 years ago, they were active during and after torrential downpours. The endemic genera *Bavayia* and *Eurydactylodes*, along with another giant gecko, *R. auriculatus*, were found in the same forest. The gecko was photographed *in situ* by Australian herpetologist **Steve Wilson**, in May 1998. Steve used an Olympus OM4Ti, a 50mm f3.5 macro lens and a single hand-held manual flash. He prefers to use a single flash, with a small pen-light attached to help focus in the dark and indicate precisely where the shadows will lie.

Steve is a supervisor in the Inquiry Centre of the Queensland Museum in Brisbane. He also works freelance as a wildlife photograper and writer. Steve has been photographing reptiles, amphibians, insects, and spiders for more than 25 years. The two main focal points of his work are the comprehensive coverage of the Australian lizards and snakes, and the herpetology of tropical islands. With co-author Dave Knowles, he published *Australia's Reptiles—a Photographic Reference to the Terrestrial Reptiles of Australia* (Collins Australia, 1988). Their book, bringing together the combined talents of some of Australia's leading reptile photographers, features a near complete pictorial coverage of Australia's lizards and land snakes. Steve's photography and articles are widely published in books and magazines throughout Australia. His next project is the publication of a field guide to the reptiles in his home state of Queensland.

Separation and imaging of Wilson's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

New Editor at the *Journal of Herpetology*

Richard Seigel, long-time Editor of the *Journal of Herpetology*, is stepping down. The journal has flourished under Rich's expert guidance, with manuscript submissions increasing each year. Effective 1 December 2000, Dr. Brian Sullivan will assume the role of Editor. Please send all new submissions and editorial correspondence to him at the following address:

Brian Sullivan
Department of Life Sciences
PO Box 37100
Arizona State University-West
Phoenix, Arizona 85069, USA

Sherman A. Minton Student Travel Awards for 2001: Appeal for Contributions

The Board of Directors of SSAR have approved one time multiple travel awards to honor the memory of the late Sherman A. Minton, M.D., which would will also serve to recognize his many important contributions in herpetology, toxinology, and medicine.

Approximately ten awards will be made to students to help defray travel expenses to the SSAR/HL Annual Meeting in Indianapolis in July 2001. These awards would be in addition to the SSAR Student Travel Awards, and will have the same criteria. The winners will be recognized in *Herpetological Review*, December 2001 issue. Donors will be recognized in appropriate ways, unless they ask to remain anonymous. Many feel Dr. Minton has a special place in their memory and we hope they will express their feelings by making a significant contribution to these awards.

Southern Torrent Salamanders are limited to headwaters of streams, seeps, and springs within coniferous forests in northern California and southern Oregon. Larvae take up to 3.5 yr to reach metamorphosis and an additional 1–1.5 yr to achieve maturation. Adults are rarely found more than 50 m from lotic waters. Timber harvesting, particularly the impacts of road-building and clearcutting on streams, is perceived as the primary threat to population viability. Effects of timber harvesting on hydrological stability, microhabitat integrity (i.e., low siltation and a rocky substrate), and temperature profiles have been identified as concerns. However, the practice of clearcutting has been strongly curtailed in this region over the past decade, and there appears to be some evidence that *R. variegatus* persists in altered habitats. Currently there are inadequate data to conclusively demonstrate that the species has low genetic variability, although it is likely the most genetically distinct (isolated) of *Rhyacotriton* species.

The Southern Torrent Salamander is listed as a species of special concern in California and as a vulnerable and sensitive species in Oregon. However, the species distribution is limited on California and Oregon state lands (2% and 1%, respectively, of the total species range). Thus, *R. variegatus* has no protection throughout the vast majority of its distribution, which is overwhelmingly on private (60%) and federal (37%) lands.

For further information, contact: Ann Chrisney, US Fish and Wildlife Service, Sacramento Fish and Wildlife Office, 2800 Cottage Way, W-2605, Sacramento, California 95825-1864, USA.

USA: Department of the Interior: The US Fish and Wildlife Service proposed to declare 193,600 ha spread over nine counties in central and southern California as critical habitat for the Arroyo Southwestern Toad (*Bufo microscaphus californicus*; now usually regarded as a distinct species, *B. californicus*). *Bufo microscaphus californicus* is a small toad native to the drainages of central (coastal) and southern (coastal and desert) California southward to Mexico's northern Baja California. The wetlands within these drainages are highly variable. Adult *B. microscaphus californicus* prefer to breed in shallow pools in low-gradient streams and are most often found near the breeding sites throughout the year (within 0.5 km). Females are quite fecund, with clutch sizes approaching 10,000. The larval period is relatively brief, lasting less than 3 mo. Males and females may reach maturity by 2 yr post-hatching, although some females may require an additional year.

Bufo microscaphus californicus is believed extirpated from more than 75% of historical localities. Habitat alteration is regarded as the key threat to continued survival. If the proposed rule is adopted, destruction and/or severe modification of the critical habitat by any federally-funded or -approved activity would be prohibited. However, less than half of the critical habitat is located on federally-owned lands.

The public comment period on the proposal ended 7 August 2000. For further information, contact: Grace McLaughlin, Ventura Fish and Wildlife Office, 2394 Portola Road, Suite B, Ventura, California 93003, USA.

USA: Department of the Interior: The US Fish and Wildlife service proposed to list the Chiricahua Leopard Frog (*Rana chiricahuensis*) as threatened under the Endangered Species Act. The Chiricahua Leopard Frog is found in central and southern Arizona and New Mexico and in the adjoining region of Mexico. The species breeds in mid- to high-elevation (between 1,000 and 2,700 m) isolated wetlands that are frequently surrounded by arid terrestrial habitats. Recent surveys for *R. chiricahuensis* have indicated that the species appears to be absent from up to 80% of historical localities in the US. Less than 80 populations are believed to remain in this country.

One threat to *R. chiricahuensis* is competition and predation from non-native vertebrates, especially centrarchid fishes, Bullfrogs, and Tiger Salamanders. In a recent study, *R. chiricahuensis* was absent from nearly all wetlands where non-native vertebrates were present, and it was present in habitats lacking the non-native vertebrates. In addition, chytrid fungus—which is believed responsible for amphibian population declines and local extinctions in Australia and Central America—has been discovered on the skin of dead Chiricahua Leopard Frogs.

Several federal agencies, Arizona Game and Fish Department, New Mexico Department of Game and Fish, private landowners, and local groups are working in consort to develop management and conservation plans for the Chiricahua Leopard Frog.

The public comment period on the proposal ended 12 September 2000. For further information, contact: Jim Rorabaugh, Arizona Ecological Services Field Office, US Fish and Wildlife Service, 2321 West Royal Palm Road, Suite 103, Phoenix, Arizona 85021-4951, USA.

International: Convention on International Trade in Endangered Species (CITES): The 11th Conference of CITES was held on 10–20 April 2000 in Kenya. The following resolutions were ACCEPTED by the delegates at the convention:

- Include Asian box turtles (*Cuora* spp.) in Appendix II.
- Transfer African Spurred Tortoise (*Geochelone sulcata*) from Appendix II to Appendix I.
- Delete Sonoran Green Toad (*Bufo retiformis*) from Appendix II.
- Include Mantella frogs (*Mantella* spp.) in Appendix II.

The following resolutions were REJECTED by the delegates at the convention:

- Include Spotted Turtle (*Clemmys guttata*) in Appendix II.
- Transfer Hawksbill Turtle (*Eretmochelyes imbricata*) from Appendix I to Appendix II.

Appendix I species are threatened with extinction and may be affected by trade. Appendix II species are not currently threatened but such status is likely unless trade is restricted.

For more information, contact: CITES Secretariat, 15 chemin des Anemones, 1219 Chatelaine-Geneva, Switzerland. telephone:(+4122) 917 8139/40, fax: (+4122) 797 3417, e-mail: cites@unep.ch.

USA: Michigan: On 24 June 2000, the Detroit Zoological Institution opened the National Amphibian Conservation Center (NACC). The NACC is a $6 million facility covering 12,000 square feet, with the goal of drawing attention to the perceived worldwide amphibian decline problem. While much of the space at NACC is devoted to exhibits featuring about 1,000 amphibians, about half of the facility is devoted to husbandry, reproduction,

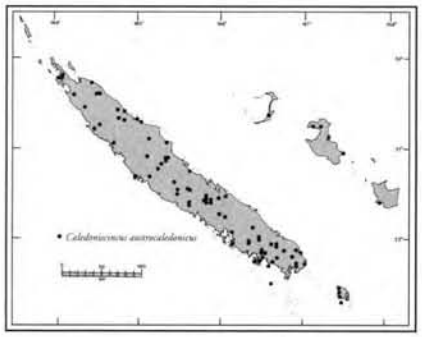
A New Book from the Society for the Study of Amphibians and Reptiles

THE HERPETOFAUNA OF NEW CALEDONIA

by AARON M. BAUER *and* ROSS A. SADLIER

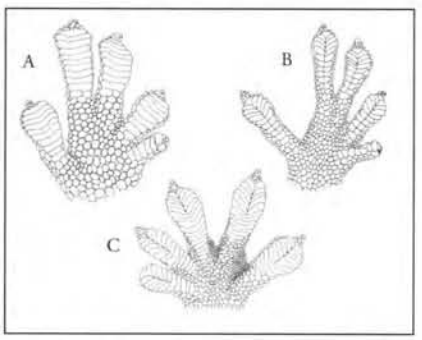
with French summaries by Ivan Ineich and 189 color photographs

NEW CALEDONIA, INCLUDING THE LOYALTY ISLANDS AND AN ASSOCIated group of smaller islands and reefs, is a French territory located in the tropical Southwest Pacific equidistant from New Guinea, New Zealand, and Australia. This ancient group of islands supports one of the most highly endemic and species-rich herpetofaunas in the Pacific region. Among the 71 species of terrestrial reptiles, 86% are endemics, and most belong to endemic genera. Despite being only 2.5% the size of New Guinea, New Caledonia has 36% as many lizard species. In addition, the New Caledonian barrier reef system, one of the largest and most diverse in the world, is inhabited by a dozen species of seasnakes. Because of the diversity of its flora and fauna and the fragility of its habitats, New Caledonia is regarded as a biodiversity "hot spot," one of the earth's biologically richest and most endangered terrestrial ecoregions.



This book—at the same time a scientific monograph and a field guide—is the first modern review of the amphibians and reptiles of New Caledonia. It covers the frogs, family Hylidae (1 species), geckos of the families Diplodactylidae (20) and Gekkonidae (6), the Scincidae (42), snakes of the families Boidae (1), Elapidae (12, all marine), and Typhlopidae (2), and the sea turtles, Cheloniidae (3). Geckos and skinks, in fact, are the most numerous and dominant terrestrial vertebrates in New Caledonia. These two groups have undergone extensive generic and specific diversification, including the world's largest living geckos (*Rhacodactylus*) and more than a dozen genera of skinks including the giant skinks (*Phoboscincus*).

The authors, Aaron M. Bauer (USA) and Ross A. Sadlier (Australia) are both noted authorities on the Pacific herpetofauna. Their extensive field work in New Caledonia began more than 20 years ago. As a result of their research, numerous new genera and species of New Caledonian geckos and skinks have been described and named, but this book represents the first synthesis of their 20 years of study.



Organization of the Book

- Geography, Vegetation, Geological History, and Biogeography
- Ecological Patterns of Terrestrial and Marine Species
- Conservation
- Humans and the Herpetofauna, including a History of Scientific Studies
- Systematic Accounts of Genera and Species:
  Keys; Synonymies; Descriptions; Distribution (spot map for each species); Natural History; Conservation Status; Remarks and Status
- Incidental Taxa, Taxa of Questionable Occurrence, and Those Erroneously Recorded from New Caledonia
- Fossil and Subfossil Species
- Literature Cited and Bibliography of New Caledonian Herpetology (more than 1000 references)
- Gazetteer of Place Names; Index to Scientific Names

The 153 color photographs of animals depict nearly every species. There are also 36 photographs of New Caledonian habitats.

Specifications: 325 pages, 7 x 10 inches (18 x 22.5 cm), plus 189 color photographs of animals and habitats on 24 plates, 47 maps, 63 figures, and 4 tables. Clothbound. ISBN: 0–916984–55–9. To be published December 2000.

PRICES: Pre-publication to SSAR members US$50; Institutions and non-members US$60. ***SHIPPING:*** USA address, add US$3; non-USA, US$6

SEND ORDERS TO: Dr. Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, 3507 Laclede Avenue, Saint Louis, Missouri 63103–2010, USA (*telephone:* area code 314, 977–3916 or –1710; *fax:* 314, 977–3658; *e-mail:* ssar@slu.edu). Please make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may also be charged to MasterCard or VISA (please provide the account number and card expiration date). SSAR membership information and a complete list of all Society publications can be obtained on request to Dr. Aldridge.

and research. The NACC is prepared to engage in collaborative projects with some of the leading conservation organizations, such as The Nature Conservancy and the IUCN's Declining Amphibian Populations Task Force.

For more information, contact: Andy Snider, Curator of Herpetology, Detroit Zoological Institute, 8450 West 10 Mile Road, P.O. Box 39, Royal Oak, Michigan 48068-0039, USA.

USA: US House of Representatives: On 11 May 2000, the House of Representatives passed the Conservation and Reinvestment Act (H. R. 701). The act would establish a Conservation and Reinvestment Act Fund, which would have a $2.825 billion annual budget. The Fund would support states' coastal conservation, development and implementation of endangered and threatened species recovery plans, federal and land restoration, among other programs. The bill was sent to the Senate where it was referred to the Committee on Energy and Natural Resources.

For more information, contact: Senator Frank Murkowski, Chairman, Energy & Natural Resources Committee, US Senate, Washington, DC 20510, USA; tel. (202) 224-6665; fax (202) 224-5301.

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 2001 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson

2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include *in situ* behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.

3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on an herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president.

5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.

6. INTERNATIONAL. Proposals may address needs in any of the above five categories, but applicants must be from countries where herpetological research has historically been underfunded, and where alternative sources of financial support are scarce or nonexistent.

7. BIBLIOGRAPHIC RESEARCH. This special category continues for 2001 thanks to a donation from Itzchak and Carolyn Gilboa. Proposals should address a major need to consult library or other information resources. The project must focus on a herpetological topic. Proposals from individuals only, accompanied by a letter of support from someone knowledgeable about the applicant and about the importance of the project.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be students AND members of the SSAR with the exception of those applying for support of regional herpetological society projects, or those applying in the international category. Membership dues must be paid (to SSAR Treasurer) no later than 31 December 2000 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. Past recipients of an SSAR GIH award in any category are not eligible for future awards. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) TITLE PAGE giving the title of the project, the name, mailing address, office and home telephone numbers and, if possible, fax number and e-mail address of the applicant. The title page should include a statement indicating that applicants "will comply with all applicable permit regulations, and adhere to all appropriate animal care guidelines in the course of conducting funded projects." (B) BACKGROUND AND OBJECTIVES of the proposed project. (C) METHODS of carrying out the project. (D) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). Include an explicit explanation of how an SSAR award of $500 would be applied toward the objectives of the project, and provide a listing of all current and pending support for the project. (E) BRIEF RESUMÉ of the applicant or project coordinator. (F) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed 1200 words, excluding title page, literature cited, resumé, and budget. Applicants must indicate word count on their application.

Applicants must designate to which of the seven categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than **31 DECEMBER 2000** to be considered. Failure to meet these guidelines may result in elimination of a proposal from consideration. The awards will be announced on or around 1 April 2001. Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Joseph R. Mendelson III, Chair, SSAR Grants-in-Herpetology, Department of Biology, Utah State University, Logan, Utah 84322-5305, USA. Tel. (435) 797-2097; Fax (435) 797-1575; e-mail: sapo@biology.usu.edu.*

A New Book from the Society for the Study of Amphibians and Reptiles

SLITHY LOVES

ILLUSTRATED CLASSIC HERPETOLOGICAL BOOKS AT THE UNIVERSITY OF KANSAS IN PICTURES AND CONVERSATIONS

by Sally Haines

84 Illustrations in Full Color

THIS BOOK IS IN THE FORM OF A GALLERY GUIDE TO A REMARKABLE EXHIBIT OF ILLUSTRATED HERPETOlogical books dating from the 16th to the 20th centuries. It results from a display arranged by the Kenneth Spencer Research Library of the University of Kansas on the occasion of the 1996 SSAR meeting held at the university. Books such as these, many of which have exquisitely handcolored illustrations by some of the greatest natural history artists, are today kept under lock and key in institutional libraries and therefore are scarcely known to most herpetologists, but the enthusiasm of the SSAR conference goers for the Kansas exhibit has encouraged us to make this printed version available. The author, Sally Haines, Associate Special Collections Librarian at the Spencer Library, is in charge of the natural history collections.

The bulk of this volume consists of full-color reproductions of illustrations from classic works together with extensive captions containing information about the authors, the artists, and the books. It is an iconography of herpetology and an essential part of the history of the field.

Organization of the Book

Myth versus Reality: the Challenge of Illustrating Amphibians and Reptiles, *by Kraig Adler*
Part I — Herpetology to 1758: The Pre-Linnaean Period
Part II — Herpetology after 1758: Beyond Linnaeus
Part III — West of Eden: New World Herps
Part IV — The Seven Deadly Sins and other Evils: Herps as Symbol
References to Historical and Biographical Works
List of All Illustrated Herpetological Works in the Spencer Library
Chronological Index to Illustrated Herpetological Works in the Spencer Library

Some of the earliest books represented in this volume are by Pliny, Abbatius, Topsell, Seba, Linnaeus, and Rösel von Rosenhof, with later ones by Daudin, Rüppell, Bonaparte, Schlegel, and Fayrer, among many others. There is a special section on books about the Western Hemisphere, including works by Sloane, Catesby, Bartram, Spix, Holbrook, Cuvier, and Agassiz. The final section, on herps as symbol, includes religious manuscripts, sea serpents, astronomical atlases, and even illustrations from the works of John Milton, Mark Twain, and Walt Kelly. Included is a detailed listing of all illustrated herpetological works in the Spencer Library, which holds one of the great collections of natural history books. This volume represents a veritable treasure trove of some of the finest illustrations of amphibians and reptiles ever produced in book form and extensive bibliographic information about them.

Specifications: 190 pages, 8.5 x 11 inches (21.5 x 28 cm), full color throughout (84 illustrations). Softcover. ISBN 0–916984–53–2. To be published December 2000.

PRICES: Pre-publication price to SSAR members US$50; Institutions and non-members US$60. *SHIPPING COST:* USA address, add US$3; non-USA address, add US$6

SEND ORDERS TO: Dr. Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, 3507 Laclede Avenue, Saint Louis, Missouri 63103–2010, USA (*telephone:* area code 314, 977–3916 or –1710; *fax:* 314, 977–3658; *e-mail:* ssar@slu.edu). Please make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may also be charged to MasterCard or VISA (please provide the account number and card expiration date). SSAR membership information and a complete list of all Society publications can be obtained on request to Dr. Aldridge.

"Coluber" Versus *"Ptyas"*: A Regrettable Tangle of Names

THEODORA PINOU

e-mail: hdowling@coosavalley.net

Ptyas is a genus of large, terrestrial snakes that range from southern China and Afghanistan through the Malayan Peninsula and the Philippines to Sulawesi (Celebes) in the east (Fig. 1). This genus (*Ptyas* Fitzinger, 1843:26) has been recognized as valid at least since Stejneger (1907:345) who used this name in his "Herpetology of Japan." It was a surprise, therefore, to encounter recent zoogeographic studies (Das 1996, 1998) using the Linnaean genus *Coluber* for the species heretofore referred to *Ptyas*. As commonly recognized, *Coluber* is a North American genus, with its closest relative, *Masticophis* Baird & Girard (1853:98), also restricted to the Americas (Fig. 1).

The European racers formerly included in *Coluber* have been shown to belong to other genera (i.e., *Hemorrhois* F. Boie, 1826, and *Hierophis* Fitzinger, 1834) by various authors in the last several decades. Inger and Clark (1943) pointed out that they differed in dorsal scale row reduction patterns, Schatti (1986 et seq.) showed them to differ in skull, vertebral, and hemipenial morphology, and Lopez and Maxson (1995) showed them to differ in mitochondrial DNA sequences. Still, the weight of Boulenger's catalogues (1893–1896) lingers on, barring full acceptance of these data.

The confusion between *Ptyas* and *Coluber* apparently was initiated by Lazell (1998:134), who stated, "There is no morphological basis for recognition of a genus *'Ptyas'* as separate from *Coluber* sensu stricto." We will show here that not only is this statement erroneous, but that Lazell's method of "proof" was, itself, invalid.

The type species of *Coluber* is *C. constrictor* Linnaeus (1758), of North America. That of *Ptyas* is *P. mucosus* (Linnaeus 1758), of the tropics and subtropics of Asia. These two species (and the other species generally associated with each of them) differ in many features. We bring additional morphological information, as well as chromosomal, immunological, and genomic data to demonstrate the distinctness of these genera.

Morphology.—*Ptyas* and *Coluber*, along with 45 or more other genera, are members of the family Colubridae (*sensu stricto*). As such, they lack hypapophyses on their posterior body vertebrae, have the typical nine caenophidian crown scutes, and have the typical colubrid asymmetrical hemipenes (i.e., mirror-image basally, similar apically), with proximal spines, distal calyces, and a simple, dextrally trending *sulcus spermaticus*.

Although these genera are somewhat similar in general morphology, they differ in body size and proportions, scutellation,

FIG. 1. Approximate geographic distributions of the colubrid *(s.s.)* snake genera *Ptyas* and *Coluber*. Note that the genus *Ptyas* (b) is restricted to the Oriental region of Asia, whereas *Coluber* (a) is restricted to Nearctic North America. [The closely related genus *Masticophis* ranges from the southern United States to Colombia and Venezuela.] The arrow indicates the range (Sulawesi = Celebes) of *Ptyas dipsas*, the major subject of Lazell's studies.

FIG. 2. Head morphology of *Ptyas mucosus* (a) and *Coluber constrictor* (b). Note especially the larger eye and the presence of a "brow ridge" in *Ptyas*. ["a" from Smith (1943: Fig. 49; "b" original (HGD-HISS) from AMNH 99107.

dentition, vertebral proportions, and hemipenial structure (cf. Ortenburger 1928:178–181, pls. 27–30, and Smith 1943:158–166).

The species of *Ptyas* (including *P. mucosus*) are much larger snakes than *Coluber constrictor*, with record lengths of *P. mucosus* exceeding 358 cm (Smith 1943:160) versus the 185.4 cm record of *C. constrictor* (Conant 1975:178). The eye in *Ptyas* is proportionately larger and has an overhanging "brow ridge" not found in *Coluber* (Fig. 2). As shown by Clark and Inger (1942), the two genera also differ in the mode of dorsal scale reduction.

The maxillary teeth differ in number (20–25 in *Ptyas*; 13–16 in *Coluber*) and size, with the two posterior teeth of *Coluber* being distinctly larger than the others, and often set off by a diastema, whereas those of *Ptyas* are more uniform in length (Smith 1943: Fig. 48, p. 159).

The vertebrae differ in proportions (reflecting the larger size of mature *Ptyas)*, even when specimens similar in size are compared: those of *Ptyas* are more massive in structure and have distinctly higher neural spines than do those of *Coluber*.

The most definitive difference, however, is in the morphology of the everted hemipenis (Fig. 3). *Coluber* (and the closely related *Masticophis*) has a distinctly bilobed organ, covered distally with distinct, closely associated calyces. *Ptyas*, in contrast, has a most unusual hemipenis, lingulate (tongue-like) in shape, with flounces basal to an almost transparent region on which the broad calyces are only faintly inscribed. There are no lobes, and, in fact, the hemipenis differs greatly from that of any other genus of snake in which the everted organ has been described. The hemipenis of *Ptyas* shows no resemblance to that of *Coluber* except in those features typical of the Colubridae *(s.s.)*: basal spines, apical calyculi, and a simple, dextrally trending sulcus.

Chromosomes.—The chromosome number for *Ptyas mucosus* has been reported (Bhatnagar 1957) as 34, showing the loss of a pair of microchromosomes from the "standard" snake chromosome number of 36, which is characteristic of *Coluber constrictor* (Baker et al. 1972). The significance of this, however, is not clear.

Molecular data.—An immunological study (Dowling et al. 1983) showed *Ptyas mucosus* to be 24 AID (albumin immunological distances) from *Masticophis flagellum*, which was only 10 AID from *Coluber constrictor*. A later electrophoretic study (Dowling et al. 1996) showed *Ptyas mucosus* to differ from *Coluber constrictor* in one of four "slow evolving" protein loci: the same distance as shown between *C. constrictor* and the Nearctic greensnake, *Liochlorophis vernalis*.

The relationships suggested above were further supported by a genomic study (Lopez and Maxson 1995) that showed Oriental *Ptyas* to cluster closely with Oriental *Zaocys* (and distantly with Nearctic *Opheodrys*), in contrast to Nearctic *Coluber*, which clustered closely with Nearctic *Masticophis* and only distantly with the Oriental genus *Gonyosoma*.

Behavior.—*P. mucosus* inflates the throat when disturbed and is reported to "growl" at an attacker (Pope 1935:222). Neither of these behaviors is found in *Coluber*.

Discussion.—Lazell (1998) gave no description of the features of *Ptyas* and *Coluber* that served to support his action in synonymizing the former, but referred to a previous paper for details (Lazell et al. 1991). Inspection of this paper shows that he had been impressed with a "Black Racer" (*Ptyas dipsas*) on Sulawesi, commenting that *Coluber constrictor* was "probably its closest living relative." It should not be necessary to point out that black populations of *Ptyas* are known from elsewhere (Smith 1943:160), and that *C. constrictor* populations are black only in the eastern United States. Western populations may be gray, blue, or spotted. Neither are genera ordinarily identified by "eye-balling" their color patterns. As emphasized some years ago by Cope (1895), Dunn (1928), Bogert (1940), and Bourgeois (1969), it is necessary to consider other characters (often internal) in identifying the taxa and establishing the relationships of snakes.

Lazell (*in* Lazell et al. 1991) did examine a specimen of *P. dipsas* in the British Museum and gave an account of his observations, including some features of the (inverted) hemipenis. He also examined inverted hemipenes of *"Coluber korros* and *Coluber mucosus"* at the Museum of Comparative Zoology (MCZ), which "revealed conditions intermediate between these simple organs [of *P. dipsas*] and the strongly bilobate hemipenes of *Coluber constrictor, C. flagellum*, and other American members of the genus."

It is understandable that Lazell found it difficult to determine the shape of the hemipenis of *P. dipsas*, because he was examining a retracted organ that had been split and spread open. The same was true of the MCZ specimens. However, inasmuch as the hemipenis of *Ptyas* has flounces and no lobes, whereas the hemipenis of *Coluber* and *Masticophis* has no flounces and is bilobed (and the shape of the organ is difficult to see in the retracted state), it is difficult to place great reliance on these observations. Further, our hemipenis preparations (Fig. 3) show that the hemipenis of *Ptyas mucosus* is by no means "intermediate." Actu-

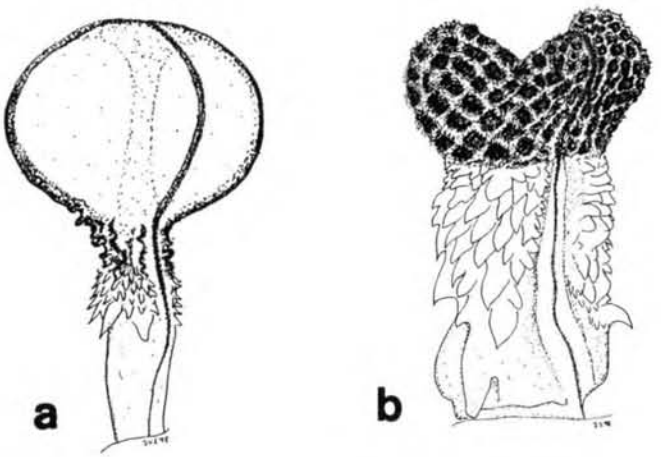

FIG. 3. Hemipenial morphology in *Ptyas mucosus* (a) and *Coluber constrictor* (b). Note especially the greatly expanded (and almost transparent) apical region of *Ptyas* in contrast to the bilobed, distinctly calyculate apical region in *Coluber*. The single *sulcus spermaticus* trends to the right (a colubrid *s.s.* feature) in both genera. [Sketch "a" from HGD Field Series #72726, and "b" from a photograph in Ortenberger (1929: Pl. 29.]

ally, it is much more different from that of *Coluber* than Lazell reported. His description of the inverted hemipenis of *P. dipsas* may be compared with Smith's (1943:160, 164) similar observations of the inverted hemipenes of *P. mucosus* and *Zaocys carinatus*. Excellent photographs of the everted hemipenes of *Coluber* (*sensu stricto*) and several species of *Masticophis* may be found in Ortenberger (1928).

Lazell's major error, however, was to choose *P. dipsas* to discriminate between the genera *Ptyas* and *Coluber*. If the data had so indicated, he might have been able to demonstrate that *P. dipsas* was actually a *Coluber*, but this would not have disturbed the status of the genus *Ptyas*. If a genus is to be synonymized, it must be done through comparisons of the type species of the genera. *Coluber constrictor* is the type of its genus, but *Ptyas dipsas* is not. *Ptyas mucrosus* is the type, and Lazell did not compare the two type species. Thus his referral of *Ptyas* to the synonymy of *Coluber* is both wrong and illegitimate. Our data clearly demonstrate that *Coluber* and *Ptyas* are not closely related to one another.

We suggest on the basis of the numerous and profound differences between the type species of these genera that *Ptyas* Fitzinger (1843) should be reinstated as a distinctive Oriental taxon, and that *Coluber* Linnaeus (1758) be restricted to the Nearctic racers, as it is commonly applied.

Acknowledgments.—We thank Janann Jenner for the sketches of the hemipenes. We also thank the two reviewers, Ted Papenfuss and Joe Slowinski (and the editor) for helping us to focus this paper on the more important elements of the review. The title is derived from that of Thomas Barbour (1917), written in reference to a somewhat similar situation.

Comments on the Restriction of the Type Locality and Nomenclature of the Chuckwalla, *Sauromalus ater* Duméril, 1856

RICHARD R. MONTANUCCI
Department of Biological Sciences, Clemson University
Clemson, South Carolina 29634 -0326, USA
e-mail: rrmnt@clemson.edu

The holotype of *Sauromalus ater* (MHNP 813) was collected during a circumnavigational voyage of the French frigate, *La Danaide*, and presented by Lieutenant M. Jaurès, without locality data, to the Muséum National d'Histoire Naturelle in Paris (Brygoo 1989). The absence of a type locality for *S. ater* has remained ever since, an acknowledged problem for taxonomists working with *Sauromalus* (Hollingsworth 1998; Schmidt 1922; Shaw 1945).

Shaw (1945), unable to study the holotype due to political conditions in Europe, believed he had uncovered clues in the literature as to its origin. In a redescription by Duméril and Bocourt (1870) and remarks pertaining to color pattern by Mocquard (1899), some details seemed to suggest that the type had originated from

one of the islands off the coast of the southern part of the Baja California peninsula. Thus, for the type locality, Shaw (1945) stated: "Not definitely known but undoubtedly one of the several islands in the southern part of the Gulf of California where this species is known to occur." Subsequently, Smith and Taylor (1950) further restricted the type locality to Isla Espiritu Santo without justification. Their restriction apparently was not based on any specific information about the holotype (de Queiroz 1995), but they may have selected this island simply because it is the largest island close to the port settlement of La Paz.

In a comprehensive systematic revision of the genus *Sauromalus*, Hollingsworth (1998) relegated *S. obesus* (Baird) 1858, and *S. australis* Shaw 1945, to the synonymy of *S. ater*. Using principal components and discriminant function analyses of meristic characters, he demonstrated substantial overlap within multivariate space among the three taxa, including the subspecies previously assigned to *obesus* and *ater*. He also described a zone of color pattern transition between *obesus* and *australis* in Baja California, which suggested conspecificity between the two mainland forms. Furthermore, based on additional evidence, he restricted the type locality of *S. ater* to southern Sonora.

Hollingsworth (1998), in an effort to determine the probable type locality of *S. ater*, drew upon both univariate and multivariate statistical data as well as color pattern information. He examined 8 meristic and 3 proportional characters, comparing the holotype with various population samples (see his Tables 10–15). He considered, in this context, only coastal and insular locations and excluded any sample area as the possible type locality if the holotype's character state fell outside the sample limits.

Herein, I argue that Hollingsworth's (1998) analysis to determine the provenance of the type specimen is unconvincing because of limitations of his data, leading to ambiguous results and an unsubstantiated conclusion. My arguments are based on the examination of his original thesis (which contains raw meristic data and color photographs of the holotype of *S. ater*), as well as the published version of his work. I also suggest that the specific name, *Sauromalus obesus* (Baird) 1858, should be conserved because the name has been widely used in the literature and the type locality is known (Shaw 1945; Montanucci, *in press*).

Hollingsworth (p. 119) asserted that there is agreement between the holotype of *S. ater* and southern Sonoran samples in color pattern, but the similarities were not stated explicitly. Hence, the reader is left only with the implication that the holotype is more similar to the southern Sonoran samples than to the Baja California and gulf island chuckwallas. In fact, Hollingsworth classified Baja California Sur, southern gulf islands, and southern Sonoran populations in the same pattern class (see his Fig. 48), and gave no indication of differences between these populations on opposite sides of the Gulf of California. Hollingsworth (p. 116), discerned five indistinct dark brown transverse bands composed of strong to weak reticulations on the dorsum of the holotype. He referred to the most distinctive of these as a "pectoral" band which is confusing and incorrect; the appropriate adjective would be "scapular" or "interbrachial." The bands are not evident in his published photographs (see his Fig. 44C), nor in his unpublished thesis (see color photograph, Fig. 57A). I could not confirm the presence of five indistinct dorsal bands in the holotype when I recently examined it. Duméril's (1856) description of the holotype does not allude to the presence of faint dorsal cross bands, and Duméril and Bocourt's (1870) redescription simply mentions that the body is covered by small black spots. However, Mocquard compared a male specimen from Baja California with the type specimen and noted, apparently in both, a faint black, transverse band in the interbrachial area just posterior to the forelimb insertions. Hollingsworth's interpretation of the color pattern may be inaccurate, as the type specimen had been in preservative over 140 years when he examined it.

In his univariate analysis of meristic characters, Hollingsworth (p. 119) ruled out certain populations as the potential source of the holotype because the holotype's value fell outside the range limits of the sample. The sample sizes for the excluded populations range from N = 3 to N = 27. One could reasonably argue that some of these samples are too small to justify their exclusion with confidence. To determine whether or not Hollingsworth was justified in excluding these localities, prediction intervals (Hahn and Meeker 1991) were calculated using the formula: Mean $\pm t_{(1-\alpha/2, N-1)}[s^2(1 + 1/N)]^{1/2}$. On the basis of the sample size, mean, and variance, the formula yields the predicted range limits within which any future observation is likely to fall with 95 percent confidence. The method assumes the sample is drawn from a population with a normal distribution; in this case, the meristic characters were found to conform to, or closely approximate, normality. The predicted range limits were calculated and the values of the holotype were then considered "future" observations which either fell within, or outside, the calculated limits.

Table 1 summarizes the statistics of dispersion and calculated prediction intervals for sampled localities which Hollingsworth excluded as the potential type locality. On the basis of number of caudals, the holotype's value (27) falls well outside the predicted range limits for the MNLND-A sample. Thus, Hollingsworth may have been justified in excluding this area as the potential type locality. The holotype's value for dorsals (32) falls very close (within rounding error) to the predicted range limits for the Isla Espiritu Santo (IES) sample, and I would hesitate to exclude this locality on that basis. The remaining localities in Table 1 have predicted range limits that encompass the holotype's values, and therefore Hollingsworth was not justified in excluding them.

Additionally, several localities have character range limits that do not encompass the holotype's value, yet they were not excluded by Hollingsworth on that basis. These include: MNLND-A (N = 27) for ventrals (145–195; holotype 144), and for brachials (41–57; holotype 39); IDANZ (Isla Danzante) for ventrals (N = 3, 127–138; holotype 144), for caudals (N = 3, 28–29; holotype 27), for supralabials (N = 3, 25–30; holotype 24), for infralabials (N = 2, 27–29; holotype 26); ISD (Isla San Diego) for ventrals (N = 7, 126–141, holotype 144), for dorsals (N = 5, 27–31; holotype 32), and for supralabials (N = 7, 22–23; holotype 24). Prediction intervals with an a level of 0.05 were calculated for these samples as well, and in all cases, the holotype's value was encompassed by the predicted limits. Hence none could be excluded as the potential type locality.

The holotype has five rostral scales, a value encompassed by the samples from islas San Diego, Santa Cruz, Danzante, and Baja California Sur, and several continental samples (see Tables 13 and 15 in Hollingsworth). On the basis of rostral counts, Hollingsworth explicitly excluded only Isla Partida Sur (limits 3–4; N = 16) and

Isla Tiburon (limits 3–4; N = 10) as the potential type locality. Using his method, however, several additional localities could be excluded: Cape region (limits 3–4; N = 19); Isla San Jose (4; N = 5); Isla Espiritu Santo (limits 3–4; N = 22); Isla San Marcos (4; N = 14), and Isla San Francisco (limits 3–4; N = 21). The rostral count data do not conform to either a normal or Poisson distribution because the values in each sample are either a 3 or a 4. The calculation of prediction intervals therefore requires the use of a distribution-free method. Using that approach, the equation for the range limits having an a value of 0.05 requires a sample size of 39 or greater (Hahn and Meeker 1991). Hence, exclusion of any of the above-mentioned localities would be unjustified because the sample sizes are insufficient to render a decision with confidence.

Hollingsworth (p. 48), stated that the fragmented rostrals of *Sauromalus* are slightly larger as compared with supralabials (see his Fig. 7 B). His illustration depicts the ideal distinction between rostrals and adjacent supralabials. However, there is variation in the size of the rostral scales due to horizontal as well as vertical fragmentation. These scales can be larger, smaller, or the same size as scales comprising the supralabial series. Also, the lateral extent of the series of enlarged scales varies (depending on the size and number of scales) relative to the position of the external nares, thus raising questions about homology. Such variation in size and position presents difficulties in distinguishing rostrals from adjacent supralabials (Fig. 1). Hollingsworth did not use any other criterion, except size, to distinguish these scales. Without discrete reference points to begin and terminate the counts, there is potential ambiguity in counting rostral scales. Hence, the character is of doubtful utility in determining the origin of the holotype. Further support for my conclusion comes from Hollingsworth's data analyses. The rostral character was not used in the canonical variates and principal components analyses in his unpublished thesis. Yet, the inclusion of the rostral count data in the published analyses did not materially affect the position of the holotype relative to known samples when the unpublished and published plots are compared (see discussion below).

Hollingsworth stated that the holotype is missing the tip of its tail, and its actual tail length/total length ratio is 0.500. He (p. 119) estimated a hypothetical tail length/total length ratio of 0.519 (by arbitrarily adding 10 mm). On the basis of actual (uncorrected) and estimated ratios, he excluded the following localities: Cape region (limits 0.522–0.529, N = 2); Isla Danzante (0.551, N = 1); Isla Espiritu Santo (limits 0.514–0.552, N = 6); Isla San Diego (limits 0.523–0.534, N = 4), and Isla Santa Cruz (limits 0.524–0.554, N = 10). However, note that using the estimated ratio, the Isla Espiritu Santo sample was erroneously excluded.

According to Hollingsworth (p. 119) the Isla Danzante chuckwallas (based on a single male and two females), have relatively long tails; the male has a ratio of 0.551. If for the sake of argument, this is accepted as near the upper limit, then a lower limit difference of 0.032 or greater would easily encompass the estimated ratio for the holotype. Indeed this magnitude of difference and greater occurs among males from Isla Espiritu Santo (0.038), Isla Partida Sur (0.039), and from Isla San Francisco (0.052); see Hollingsworth's Table 10. The same argument can be made for Isla San Jose (limits 0.540–0.554, N = 2) which was not excluded by Hollingsworth on the basis of the tail length ratio.

The estimated tail length ratio in the holotype exceeds the lower limit ratios of Isla Santa Cruz and Isla San Diego samples by only 0.005 and 0.004 respectively. Assuming a comparison between the holotype and another specimen of identical total length, these ratio differences convert to an actual measurement difference of only 1.33 mm for the Isla Santa Cruz sample, and 1.07 mm for the Isla San Diego sample. These differences are exceedingly small, and errors of this magnitude can be expected in repeated measurements of these lizards using a metric ruler with 1 mm increments. Furthermore, a difference of 1 mm falls within the 90% confidence interval of Hollingsworth's estimate (he added 10 mm to the tail length). Hence, in all of these cases, the exclusions are unjustified because: 1) the holotype's tail length can only be estimated; 2) the holotype's ratio falls outside the limits of samples by a very small value that is within the range of experimental error; 3) the sample sizes are inadequate to calculate distribution-free prediction intervals with 95% confidence (N = 39 or greater would be required).

TABLE 1. Localities excluded as the source of the holotype of *S. ater* with data from Hollingsworth (1998). See text for calculation of prediction intervals. Localities are: Baja California Sur (MNLND-A); Cape region (CAPE); Isla Espiritu Santo (IES); Isla San Marcos (ISM); Isla San Francisco (ISF); Isla Santa Cruz (ISCRZ); Isla San Jose (ISJ).

Character	N	Mean	S^2	Observed Range	Holotype Value	Predicted Range

* Table 14 in Hollingsworth gives N = 231 which is in error based on his unpublished thesis.

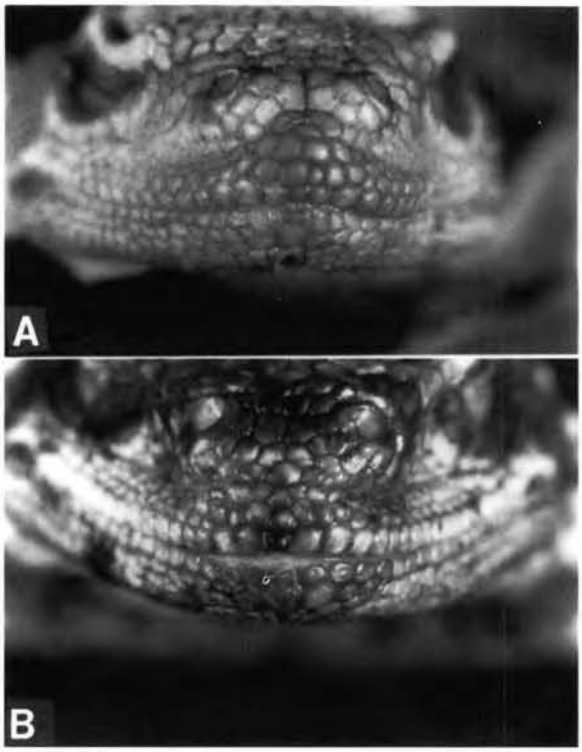

FIG. 1. Examples of the difficulty distinguishing rostral and supralabial scales in *Sauromalus obesus*. (A) Three small scales in the rostral area flanked by large scales of the same size as those in the supralabial area (RRM 2869). (B) Small, dark median "rostral" scale, flanked by larger scales showing little or no size diminution into the supralabial area. One slightly larger scale interrupts the size continuity on the anatomical left (RRM 2793). Photos by David H. Lewis.

Hollingsworth also linked the holotype with Sonora because it has four postrostrals, a number typical of Sonoran populations (limits 3–4), whereas Baja California Sur and the southern gulf island chuckwallas have 2–3 postrostrals. However, without information on sample sizes, the usefulness of this character is difficult to judge. Furthermore, it is unclear if Hollingsworth is suggesting a discrete character difference between these populations (which could be used to diagnose species), or a non-discrete statistical difference, which may have dubious value in determining the type locality.

My analysis of Hollingsworth's univariate statistical comparisons indicates that due to inadequate sample sizes most insular and southern coastal mainland sites cannot be ruled out as the source of the holotype. Furthermore, although Hollingsworth employed an objective method to exclude certain localities, the univariate approach has an intrinsic weakness. It is possible for a specimen from a given population to exceed the sample range limits for one character, while conforming to a series of others. Thus, to exclude an unknown individual from a population sample on the basis of a single character is inherently risky. On the other hand, a multivariate approach to determine the origin of the holotype is theoretically much more robust because it takes into consideration all the characters used in the analysis.

The multivariate classification analysis places the type specimen with the southern Sonoran sample (Hollingsworth, p. 119 and Appendix V). This assignment has a posterior probability of 0.51; in other words, the level of confidence that the holotype originated from southern Sonora is 51 percent. The next highest probability is 0.22 for Isla San Diego.

However, the result of this classification analysis is contradicted by the discriminant function analysis dispersion plot (Hollingsworth, p. 137, Fig. 51). In that plot, the holotype falls within the dispersion polygon for Isla San Francisco, lies adjacent to the boundary of Isla San Marcos, and slightly farther away from the boundary of the southern Sonora sample. The principal components analysis plot (Hollingsworth, p. 139, Fig. 52) also does not clearly support the classification analysis. Although there is considerable overlap among taxa, the type specimen appears to be positioned well within the cluster of points representing *Sauromalus ater ater*, but falls marginally relative to those points identified as *S. obesus townsendi* of Sonora along the first principal axis. In accepting the result of his classification analysis, Hollingsworth did not attempt to reconcile the apparent discrepancies between it and the discriminant functions (canonical variates) and principal components analyses, nor did he explain why he favored the former over the latter two.

Hollingsworth did not depict the position of the holotype relative to known samples in plots based on additional axes (e.g., third and fourth canonical and principal components axes). Presumably, if these plots had supported his hypothesis of a Sonoran origin for the holotype, he would have published them or provided some discussion. Plots for the first and third axes for the canonical variates and principal components analyses can be found in his unpublished thesis. However, the position of the holotype is not indicated in these plots. The axes beyond the first two explain progressively smaller percentages of the total variance in the data. Thus, even if the holotype were positioned within the dispersion polygon for Sonora using subsequent axes, this result would be less convincing than that based on the first two axes. Hypothetically, an exception would be conflicting results using PC I and PC II versus PC I and PC III, because in Hollingsworth's data the percentages for PC II and III are nearly identical (see his Appendix V).

Hollingsworth (p. 137) stated that only 60.8 percent of the males could be classified into their respective populations, and (p. 138) that the principal components analysis yielded no separation between taxa and no groups could be designated. In view of these statements, his decision to restrict the type locality to southern Sonora appears to be indefensible. In my opinion, no evidence has been presented by Hollingsworth that definitively supports the designation of southern Sonora as the type locality to the exclusion of the southern peninsula and adjacent gulf islands of Baja California. I acknowledge that southern Sonora must be given consideration. But without additional evidence, I believe the provenance of the holotype remains open to speculation and conjecture.

The name *Sauromalus ater* was proposed by A. Duméril in 1856, and therefore has priority over the name *S. obesus* (Baird) 1858. But, *S. ater* has been little used and is essentially restricted to papers published in technical journals, whereas the name *S. obesus* appears in numerous papers and books, ranging from technical to popular. Beaman et al. (1997) listed 626 titles of technical and popular articles pertaining to the genus *Sauromalus*, and several others have since been published. Out of this total, the name *S.*

ater is used in approximately 46 titles. Most of these (34) were published before 1950, and nearly all concern taxonomy or distributional records.

The literature for *S. obesus* is far more extensive by comparison, and the number of publications in which the name is used is conservatively estimated to be about 90 percent of the total, or over 550 works. Even in papers that deal with another species of *Sauromalus*, e.g. *S. varius* or *S. hispidus*, the name *S. obesus* often appears in reference to the common western chuckwalla. *Sauromalus obesus* is almost exclusively used in the literature dealing with physiological ecology of chuckwallas (about 133 papers), most of the ecological studies (about 71 papers), as well as morphological studies (about 92 papers).

Clearly, the name *S. obesus* has had a long history of usage to the present, and is deeply entrenched in both the scientific and popular literature. Replacing it with the name *S. ater*, which is barely known outside the field of lacertilian taxonomy, would result in permanent and serious havoc. Therefore, in the interest of nomenclatural stability in herpetology, I intend to petition the International Commission on Zoological Nomenclature to conserve the long used and well known specific name of *Sauromalus obesus*.

Acknowledgments.—I am grateful to Bradford Hollingsworth for several courtesies and for graciously providing me with a copy of his original thesis. I also thank Aaron M. Bauer, Kevin de Queiroz, Hobart M. Smith, and two anonymous reviewers for their critical comments on previous drafts of this paper. Special thanks go to John R. Cummings for helpful discussion and Marie Coffin for statistical assistance. Ivan Ineich, Museum National d'Histoire Naturelle, Paris, kindly lent the holotype of *S. ater* for study.

Saudi Arabian waters are home to several green turtle (*Chelonia mydas*) populations in need of management and conservation. In the Arabian Gulf a large nesting population utilizes four small Saudi Arabian islands (Miller 1989), but the Red Sea has, until now, remained a poorly studied region in terms of sea turtle nesting and foraging populations. Frazier and Salas (1984) indicated diffuse populations along the Egyptian shoreline, but also highlighted some of the difficulties of working in the region. In 1982, a comprehensive survey of turtle population in the Arabian region highlighted even further the dearth of information in the Red Sea, linked to lack of response to questionnaires and lack of available data to report on by several governments (Ross and Barwani 1982). Along the 1800 km Saudi Arabian Red Sea mainland coast, green turtles nest almost entirely at Ras Baridi, a 6 km stretch of the shoreline on five isolated sandy beaches (Miller 1989; Pilcher et al. 1990). The nesting beaches' close proximity to a sizable cement factory and its associated environmental degradation prompted research and conservation efforts by the National Commission for Wildlife Conservation and Development (NCWCD). The effect of the cement dust on hatching success were described by Pilcher (1999). The area immediately south of the main Ras Baridi headland was also the only confirmed feeding and foraging range for green turtles in the Saudi Arabian portion of the Red Sea (Pilcher 1992), although the Farasan bank in the south was believed to support a similar foraging population.

The objectives of this project were to conduct seasonal surveys from 1989 to 1992, to detail for the first time the general reproductive biology, inter-seasonal migrations, reproductive output and status of green turtles at Ras Baridi, and to determine the morphometric characteristics of the nesting population, eggs, and hatchlings.

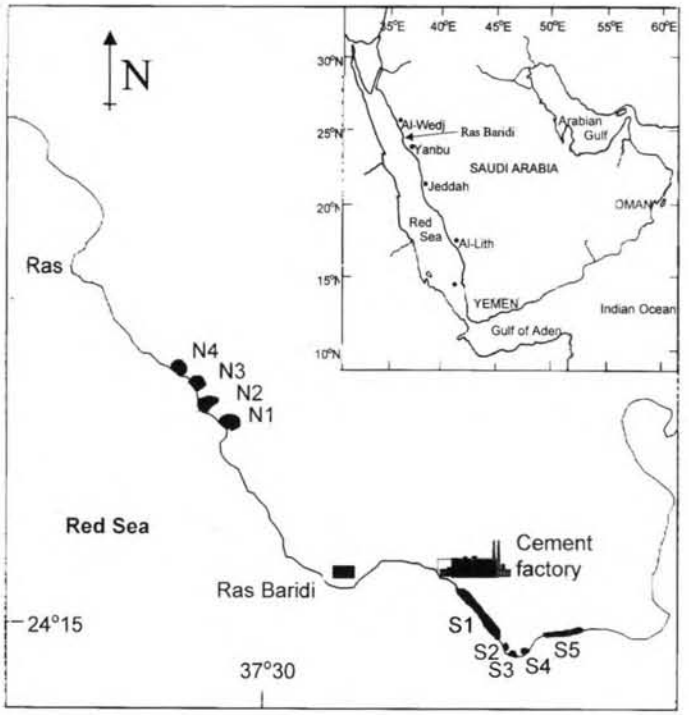

FIG. 1. The Ras Baridi rookery in Saudi Arabia. Nesting beaches N1 to N4 are north of the cement factory, S1 to S5 are the nesting beaches south of the factory and in the path of wind-blown cement dust.

METHODS AND MATERIALS

The Ras Baridi rookery is located 70 km north of Yanbu Al-Bahr and extends from 24°14'N, 37°45'E to 24°26'N, 37°25'E (Fig. 1). There are no villages and the area is only infrequently visited by local fishermen. The only industrial activity is a cement factory located south of the Ras Baridi headland. Four nesting beaches are located north of the cement factory on which a minor amount of nesting occurs (N1 to N4). South of the cement plant there are five nesting beaches on which the majority of nesting takes place (S1 to S5). An exposed fossil reef extends inland 500–1000 m and forms a flat ledge 2–3 m above sea level. Among this formation small sandy coves make up the nesting beaches, which range from 10 m to 1.2 km in length and 2–500 m in width with sand depths ranging from 0.5 to 2 m. The beach surface is littered with rocks, and vegetation is comprised of small halophytic plants that form a partial cover above the dune line. Hard, raised limestone reefs form the borders to all the beaches which effectively seal the sides, leaving only the rear open to occasional vehicle passage and turtle and hatchling movement. A fringing reef 20–200 m offshore forms a lagoon that ranges from 20 cm to 5 m in depth. The nesting beaches consist of fine to medium-coarse sands mixed with cement dust. Since the cement factory started operations in 1979, prevailing winds have blown the cement dust toward and over the main nesting beaches, and nesting activities by sea turtles have mixed the original sand with the fine (< 0.15 mm particle size) cement dust that now penetrates down to 1 m below the surface.

Surveys were carried out from June to December 1989 to 1992 to estimate the number of adult females, egg production and subsequent hatchling emergence, along with details of the nesting activity. Study periods spanned peak nesting, incubation and emergence. Data were collected on adult, egg, and hatchling morphometrics, nesting activity and frequency, and on the effects of cement dust from the nearby factory.

Turtles were tagged, measured, and weighed after oviposition. Adult females were tagged with two titanium tags (Stockbrands Pty. Ltd.) applied between the first and second proximal scales (in 1989), or through the first scale (in 1990–1992) on the trailing edge of the front flippers. On one of the tags the address was printed in Arabic and on the other it was in English. Turtles were weighed using a Salter hanging spring balance (± 0.5 kg). Measurements were made using a flexible fiberglass tape for curved carapace length and width, head width and tail length (± 0.5 cm) and with a large set of calipers for straight length and width (± 0.5 cm). Measurements followed Limpus et al. (1983) except tail length which was measured from the tip of the tail to the tail/carapace junction.

In 1989 ten nests were dug up to determine average sizes and weights of the eggs. Each egg was marked on the top of the shell as it was removed from the nest to reduce the chances of rotation through the vertical axis, as this movement is known to be a cause of egg mortality (Limpus et al. 1979). During the 1990–1992 monitoring periods, ten eggs were collected as the female continued to lay the balance of the clutch. These were weighed and measured and returned to the nest prior to the conclusion of egg-laying, to reduce the chances of movement-induced mortality and promote egg survival. After a customary 55–60 day incubation period, further surveys were carried out to determine incubation and emergence success. Hatchlings were collected on the beach and their tracks were traced back to the point of emergence, whereupon the nest was dug up to determine the total number of egg shells, number of infertile eggs and partially developed embryos. Eggs and hatchlings were weighed on a Sartorius electronic balance (± 0.1 g). The maximum egg diameter and hatchling Straight Carapace Length and Width were measured using dial-scale calipers (± 0.1 mm).

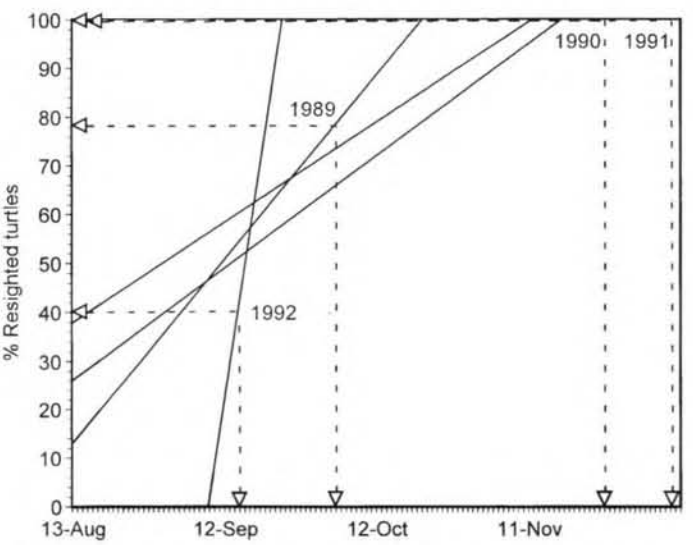

FIG. 2. Renesting trends during the four-year project. Solid lines represent linear trends (based on regression) in the percentage of recaptures with each season. The intersection of these trends with the end of each monitoring period (dashed lines) represent the estimated percent of turtles tagged during each season (see text for details).

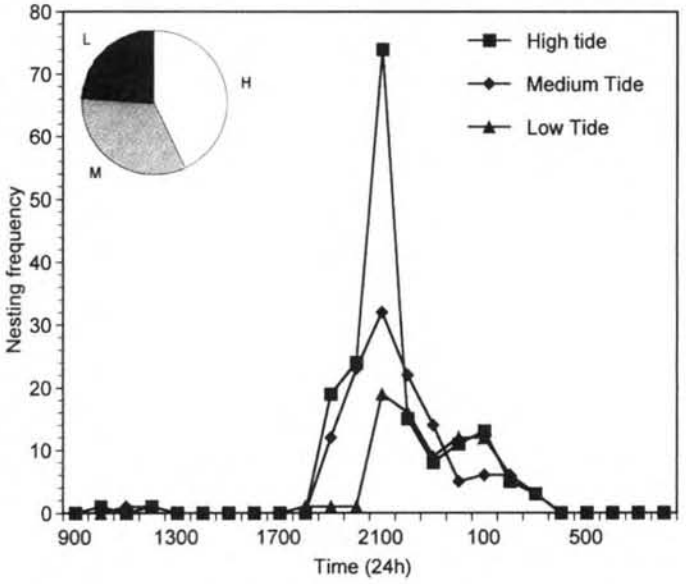

FIG. 3. Nesting distribution over 24 hours at different tide heights.

RESULTS

Remigration and Nesting Dynamics.—Fifteen out of the 194 turtles that were recorded on the beaches between 1989 and 1992 returned for second nesting seasons. Five of these had been previously tagged in 1987 by J. Miller. The maximum remigration interval (between nesting seasons) was four years, the minimum was 1 year (mean = 2.7, SD = 0.87, N = 6). Of the remigrants, four turtles returned to nest at the same beach they were originally tagged on, and five moved less than 50 m between S2 and S3 (Fig. 1).

The number of turtles nesting between 1989 and 1992 fluctuated between 14 and 99 individuals per year. Due to the length and variation of monitoring periods it was not possible to tag and count every nesting female, therefore, based on simple mark-recapture probabilities, straight line regressions of renesting trends were used to estimate annual nesting population size (Fig. 2).

It was estimated that a large portion of the turtles that would have nested each season were encountered during the surveys, based on simple mark-recapture probabilities. After turtles were tagged and allowed to return to the internesting habitat, they were assumed to mix evenly among non-tagged individuals. During subsequent nesting attempts, the ratio of tagged turtles to non-tagged turtles was used to estimate the percentage of that season's turtles that had been tagged up to that point in time.

In 1990 and 1991, it was estimated that 100% of the nesting turtles were tagged (horizontal dashed lines, Fig. 2) by the end of the monitoring period (dashed arrows, Fig. 2). In 1989, the percentage of tagged turtles at the end of the season was estimated to be 78% and in 1992 it was 40%. These estimates assume that the turtles that were not observed during the nesting periods behaved in a similar manner and renested at similar frequencies to those that were observed. Extrapolation from the number of turtles that were tagged in 1989 (59), suggests the total nesting population size may possibly have been 76. Similarly, the estimated total nesting population sizes for 1990, 1991, and 1992 were 14 (100% recaptured), 99 (100% recaptured), and 53 (40% recaptured) respectively.

Nesting occurred from July to November and peaked during September. Although beaches were frequently monitored during daytime, turtles were rarely encountered prior to 1700 h. Beaches were patrolled each morning to find signs of any nesting not recorded the night before. Late afternoon nesting was never recorded, although by early evening a slight amount of nesting took place. Most nesting (96.7%) took place between 1900 and 0200 h, with a large proportion (46%) emerging during high tide (Fig. 3).

No significant differences were found between renesting intervals among the years ($-1.73 < z < 1.03$, $P > 0.05$). Overall, recaptures indicated a renesting interval of 12.1 days (SD = 2.68, range 5–20, N = 147). These figures exclude turtles returning to the beach within five days as it is believed these attempts follow unsuccessful first nesting attempts (Mortimer and Portier 1989). They also exclude turtles nesting more than 20 days after first sighting as the turtles might have nested during this period but not been observed. Classified into 1st, 2nd, 3rd, and 4th renesting occurrences, the internesting intervals were 13.1 (SD = 2.47, N = 74), 10.6 (SD = 2.15, N = 45), 10.2 (SD = 1.58, N = 14), and 11.4 (SD = 1.14, N = 5) days, with a significant shortening of interval after the first renesting occurrence ($z_{0.05} = 5.899$, $P < 0.05$) (Fig. 4).

Turtles nested 1–5 times in a season (mean = 1.9, SD = 1.88, N = 118), but 32.5% were found to nest only once. In 1991 and 1992, only five nesting attempts were missed (determined by track counts during the day), virtually eliminating the possibility of recording error. Most nesting (70%) took place on the two larger beaches south of the cement factory, S1 and S5. Only 6 nesting attempts (1.04%) were documented on the beaches north of the cement factory during the four years, though the beaches are similar in shape, size, and sand type. The fixation for a single headland and its five beaches, and lack of movement to nearby beach clusters, suggest there may be no nesting by these females at any other location. Of 194 turtles, 77 (40%) returned to the same nesting beach on all nesting attempts, again mostly on beaches S1 and S5, although 16

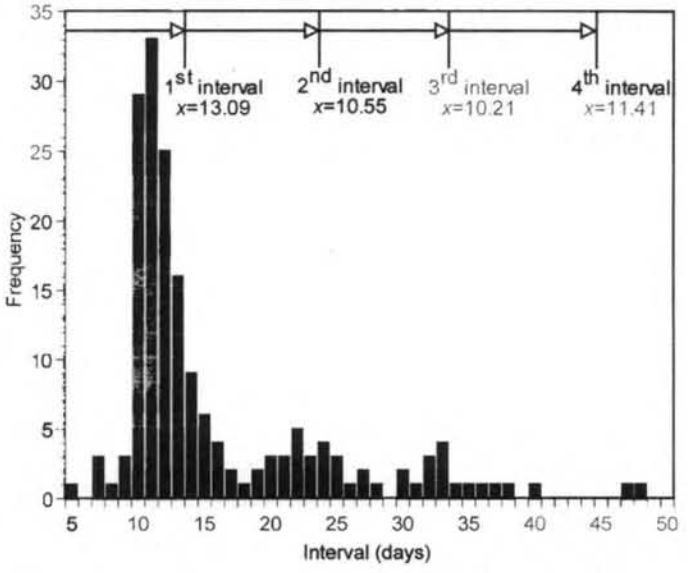

FIG. 4. Renesting intervals between successful nesting attempts for green turtles at Ras Baridi, 1989-1992. *x* represents the numerical mean of each recapture interval.

turtles also returned to within 30 m of their original nest location on the small beaches S2 and S3 (Fig. 1).

Adult Morphometrics and Growth.—Sizes and weights of turtles were pooled from the four annual data sets (Table I). No significant differences were detected for curved carapace length (CCL) (1.294 z -0.357) and weight (-0.778 z -0.203) over the four years which, in the absence of sufficient other long-term nesting data, suggests a degree of uniformity among nesting aggregations with a proportional number of recruits and seasoned nesters. Carapace sizes ranged from 88 cm to 115 cm (CCL) and were found to be normally distributed with a small number of recruits and older age/size classes (Fig. 5). Average female straight carapace length was 97.2 cm (SD = 5.75, N = 199) and average weight was 124.7 kg (SD = 16.28, N = 72). The smallest egg-laying female (smallest size at maturity for the site) measured 89.0 in CCL and 78.0 cm in SCL, and weighed 82.0 kg.

The relative shape of the carapace may be indicative of a predator avoidance strategy related to hydrodynamics. Because sizes alone may not completely reveal the character of the turtles' carapace, an index of carapace shape (domed vs. flat) was also calculated. A relative index of carapace curvature among 100 females (as per Balazs, 1980) yielded a ratio (curved to straight carapace length) of 1.08 (± 0.05, range 1.01–1.24). Predominant adult male and female coloration was dark brown/green with occasional highlights of olive green and yellow.

Egg and Hatchling Morphometrics and Clutch Viability.—Weights and diameters were measured for over 700 eggs, and clutch size was determined in 66 cases. No significant differences were noted between the four years (for weight and diameter: $z < 0.5$, $P < 0.01$). The average clutch size was 99.7 (SD = 29.06, range 7–158) and the number of small, yolkless eggs per clutch was 0.4 (SD = 1.82, range 0–19). Eggs averaged 51.3 mm maximum diameter (SD = 6.8, N = 717) and weighed 44.5 g (SD = 2.2, N = 717) (Table 1). Regression analysis found no significant relationship between total clutch size and number of small deformed eggs ($r = 0.255$, N = 43).

The mean incubation period was 59.7 days (SD = 2.9, range 50–82, N = 39 nests). Incubation success in 28 nests from which hatchlings emerged averaged 80% (SD = 16.0, range 32–98.9) inclusive of infertile eggs (which averaged 10.1 per clutch, SD = 8.1) but exclusive of small deformed yolkless eggs.

Samples of six to ten hatchlings were taken from 70 nests and hatchlings weighed an average of 24.6 g (SD = 3.8, N = 847). Mean SCL was 48.7 cm (SD = 2.5, N = 847) and mean SCW was 37.8 cm (SD = 3.0, N = 847) (Table 1). These fall within the narrow 2–3 mm and 4–5 g variation that is common to green turtle hatchlings (Hirth 1997).

Mortality.—Mortality of adults on nesting beaches was rare. Three turtles (1 on beach S2 and 2 on beach S3) were found dead after having wandered beyond the beach, across the fossil reef and then fallen off the edge to land inverted. Nesting females were subject to in-water predation as evidenced by numerous scars and several missing rear flippers and although the nearby waters were home to a number of species of sharks, no conclusive data exists that suggests they were actually responsible. No land-based predation was noted on adult turtles.

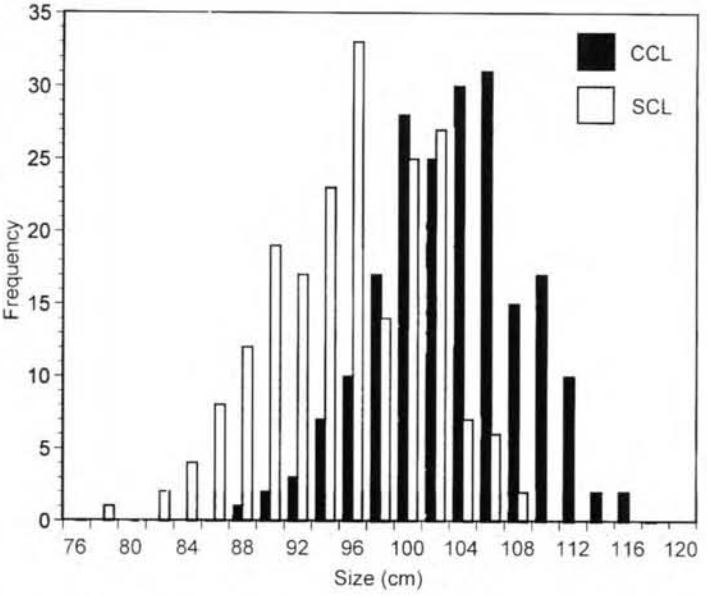

FIG. 5. Size class distribution of nesting females at Ras Baridi. CCL = Curved Carapace Length; SCL = Straight Carapace Length.

On one occasion a fisherman was found searching for eggs, but our presence during the nesting seasons probably dissuaded further egg collection. Only a small number of fishermen were active in the area, and they collected eggs infrequently. Due to religious customs, adult turtles are not eaten by Saudi nationals.

The beaches are frequently patrolled by falcon hunters during the nesting season as it coincides with the migration of peregrine falcons (*Falco peregrinus*), a highly prized catch in the Kingdom. Though not a direct threat to sea turtles, these falconers cross the beaches in 4x4 vehicles at day and at night following the birds. Several times dead hatchlings were found in the tire tracks of these vehicles, and adult turtles were disturbed by the moving lights on the nesting beaches (particularly on S1).

A frequent predator on the beaches was Rueppel's fox (*Vulpes rueppelli*). The foxes (estimated to number 5–10 in the area from personal observations) frequently dug up nests for eggs and hatchlings. Foxes waited for the hatchlings to emerge, and then decapitated as many hatchlings as possible before they reached the sea. The foxes then returned to consume those that they had

TABLE 1. Summary of morphometric data for adult female green turtles at Ras Baridi. SD = Standard Deviation: N = Sample size; CCL = Curved Carapace Length; CCW = Curved Carapace Width; SCL = Straight Carapace Length; SCW = Straight Carapace Width; PL = Plastron Length; PW = Plastron Width; TL = Tail Length; HW = Head Width, all in cm; WT = Weight (kg).

	CCL	CCW	SCL	SCW	PL	PW	TL	HW	WT
Mean	105.1	94.6	97.2	74.9	82.7	74.4	20.2	13.7	124.7

killed. In this manner it was believed they were able to consume more hatchlings than if they had consumed one at a time after emergence. Ghost crabs (*Ocypode saratan*) were found to feed on hatchlings, but were never observed to actively chase seaward-bound hatchlings, nor were their burrows ever found infiltrating exhumed nests.

Discussion

Sea turtles share a similar life cycle and general reproductive biology with only slight variances among species. An extensive literature exists on the biology, reproductive techniques, egg development, hatchling behavior, and morphology for sea turtles (reviewed by Hirth 1997). One important aspect of sea turtles' natural history is that they must emerge onto dry land to lay their eggs. At this point they are vulnerable to a number of threats, including harvesting by man and habitat degradation. Because turtles are not generally known to change nesting sites in the course of their lifetime (Limpus et al. 1983b), the protection of the nesting habitat and the preservation of normal nesting behavior at that site are critical to ensuring the long-term survival of the nesting population. For this reason the protection of the only large mainland nesting aggregation along the Saudi Arabian Red Sea coastline is considered vital. Although not as numerous as the Oman and Arabian Gulf populations, the Ras Baridi turtles represent the only known major aggregation on the Saudi Red Sea.

Remigration and Nesting Dynamics.—The nesting process was found to be consistent with that generally reported for green turtles (reviewed by Hirth 1997). Turtles were not found to deviate from the normal pattern of nesting at night, although a few nesting incidences were recorded during daylight hours. In general turtles nested at, or just before, high tide. It is thought that this occurs because at high tides females have the most time to complete the nesting process and return to deep water before being stranded on the reef or in the shallow lagoon as the tide recedes. At low tides, the fringing reef that borders the beach is exposed and difficult to cross.

In general, turtles displayed a high degree of site fidelity over remigration intervals, comparable to that found on Ascension (Mortimer and Portier 1989) and in Australia (Limpus et al. 1992). Because the nesting site consists of only a few small beaches, and no nesting was recorded on similar beaches that exist nearby, it is believed that the nesting beaches at Ras Baridi are the only beaches upon which these turtles emerge to lay eggs.

Although migrations between foraging and nesting sites have been well documented for this species (Balazs 1976; Mortimer and Carr 1987), no movements of this type have been recorded in the Red Sea. Neither FAO (1973) or Hirth and Carr (1970) indicate any movements into the Red Sea from turtles tagged in the Gulf of Aden, Oman, and the eastern coast of Somalia in their reports on long-distance migrations for green turtles in this region. Similarly, no tags have been returned from these areas after tagging programs within the Red Sea. Ross and Barwani (1982) report on the only known instance where a tag originating in Masirah was returned from Ethiopia, though the turtle was probably caught off the Somali coast (P. Ross, pers. comm.). The cyclic ocean currents within the Red Sea (Edwards 1987) and the relatively narrow Straits of Bab Al Mandeb (29 km), are suggested as possible explanations for the lack of movement between the two water bodies. The only two sites known or thought to support significant numbers of foraging turtles in Saudi waters are at Sharm Al Khaur (next to Ras Baridi) and Farasan (south Red Sea) (pers. obs.). Miller (1989) suggests a more extensive distribution of foraging areas, but in aerial surveys of the region during the present study only the two mentioned above (also noted by J. Miller) had significant numbers of resident turtles.

Green turtles feed primarily on seagrass (Bjorndal 1985), and whereas along the Red Sea the seagrass distribution is near-continuous, pastures are sparse in the northern latitudes and only moderately dense from mid- to southern latitudes along the Saudi Arabian coastline, and the presence of turtles is rare (Price and Crossland 1988). Frazier and Salas (1984) indicate that foraging sites along the Egyptian Red Sea may also be rare. If this case proves true, the few areas that Red Sea-resident turtles do use will warrant strong and effective protection, particularly if turtles do not emigrate from the Red Sea to forage.

Adult Morphometrics.—The smallest egg-laying female (smallest size at maturity for the site) measured 89.0 cm in CCL and weighed 82.0 kg, comparable to that of the Arabian Gulf (CCL 89.5 cm; Miller 1989) but larger than that of Yemen (CCL 68.2 cm; Hirth and Carr 1970). The relative index of carapace curvature among Ras Baridi nesting females was similar to the Arabian Gulf turtles (1.07 ± 0.02, data extracted from Miller 1989), while in general turtles were larger than that reported for Oman (83.9 cm; Ross 1985) and Yemen (83.2 cm; FAO 1968), where turtles nest on beaches facing the Indian Ocean.

The larger size of the nesting females within the Red Sea may be explained by the fact that nesting populations on both coasts of the Red Sea are small in comparison to those nesting on the southern coast of the Arabian peninsula. These populations possibly exert smaller pressure on foraging grounds, eliminating food as a limiting factor to growth. It is also possible that little or no migration occurs from the Red Sea to the Gulf of Aden or vice versa, based on the lack of tag returns and that the energy formerly used for migration is invested in growth.

Reproductive Output.—Average clutch size was found to be low on a global scale, but similar to other Arabian region findings (Oman: 97–103, Ross and Barwani 1982; Arabian Gulf: 87–89, Miller 1989; Yemen: 88.1, Hirth and Carr 1970). However, the incubation period was consistent with that found at other rookeries (48–72 days: Hirth 1971), and the hatching success was high on a global scale.

It must be noted though, that the reproductive success calculations involved only nests from which hatchlings emerged, and the overall rate for the rookery was believed to be lower because up to 40 % of nests do not hatch at all. Egg and hatchling survival at the site was addressed through a separate series of trials.

Mortality.—A major cause of mortality was the cement dust and light from the cement factory. During investigations in 1992, hatchlings from beaches S1 and S2 were attracted to the light as they emerged and an average of 9.3 dead hatchlings were found each day along the factory perimeter fence for 28 days (260 hatchlings) (Pilcher 1999). During this study it was found that the partially-processed cement dust was carried by prevailing winds to the five southern nesting beaches, and had mixed with the sand over 17 years of turtle nesting to penetrate to depths over 1 m. The

cement dust in the sand, combined with ambient moisture, formed a domed ceiling above the nest, in effect creating an artificial pocket from which hatchlings were often unable to escape. It was believed that this accounted for up to 40% of hatchling and nest mortality (Pilcher 1999). The overall hatching success rate in 1989 (including nests from which no hatchlings emerged) was 39%. In 1990 and 1991, when concentrated efforts were made to assist nests that might not hatch due to cement dust clogging, overall hatching success rose to 71% and 81% respectively (Pilcher 1999).

A reduction in light emission would reduce the number of hatchlings disoriented in their journey to the sea, but a reduction in cement dust output would only partially solve the problem encountered by emerging hatchlings. The dust that has accumulated over 21 years is now mixed with the sand so that even if there was a complete reduction in cement dust output, the nests would still be subject to the same problem. A nest marking and assisted emergence program is one of the only practical solutions at this time.

The effect of artificial lights on hatchling orientation have been well documented (Lohmann et al. 1990; Salmon and Witherington 1995) and the brightness of the factory lights are similar to, if not brighter than, those from beach-front condominiums and other residential areas. It is suggested that a reduction in light output, by shielding the security floodlights and by eliminating many of the fluorescent lights at underutilized areas would greatly increase the numbers of hatchlings that reached the sea.

Acknowledgments.—This project is indebted to H.R.H. Prince Saud Al-Faisal and H. E. Prof. Dr. Abdulaziz Abuzinada for their support. We would also like to thank Omar Khusheim, Anas Sambas, Ahmed Al-Mansi, and Steve Oakley for their assistance with the fieldwork. This project was entirely funded through the IUCN/NCWCD National Saudi Arabian Wildlife Conservation Programme. All assistance is gratefully acknowledged.

e-mail:bruce.wing@noaa.gov

Four species of marine turtles have been observed in Alaska waters (Bane 1992; Hodge 1979, 1981, 1992; Wing and Hodge 1998). Although occurrences of marine turtles in Alaska have been reported geographically, there is no published information on the frequency of occurrence and abundance of turtles in Alaska. In this paper we discuss the frequency and abundance of marine turtle occurrences in Alaska waters since 1960.

Reports of marine turtles were gathered from several sources. The senior author compiled records from museums, correspondence, interviews, and questionnaires distributed to fishermen, biologists, and school teachers in Alaska coastal communities. The junior author compiled records from field notes, correspondence, newspaper articles and reporters, biologists and records in the herpetological collection of the National Marine Fisheries Service Auke Bay Laboratory, Juneau, Alaska. The authority/source references for all occurrences are in the Auke Bay Laboratory herpetological collection records.

Mean August sea surface temperature records from Auke Bay, Alaska (Wing and Pella 1998) were used to characterize environmental conditions for years in which turtles occurred in Alaska. Mean sea surface temperatures within one standard deviation (1 SD) of the long-term mean were considered normal-water years. Years with mean sea surface temperatures 1 SD or higher above the long-term average were considered warm-water years; years with mean sea surface temperatures 1 SD or lower below the long-term mean were considered cool-water years. All Alaska marine turtle records were plotted in relation to warm-water year, normal-water year and cool-water year occurrences.

Alaska marine turtle occurrences since 1960 include 19 leatherbacks, *Dermochelys coriacea* (including one sighting of two turtles), 9 greens, *Chelonia mydas*, 2 Pacific Ridleys, *Lepidochelys olivacea*, 2 loggerheads, *Caretta caretta*, and 2 unidentified hard shell turtles (Table 1, Fig. 1). Marine turtles have been observed in Alaska waters 14 of the past 39 years (Fig. 2) during all months except February and April (Fig. 3). Stinson (1984) and Starbird et al. (1993) identify a 'turtle season' in the northeast Pacific Ocean as July, August and September. Our data identify a similar Alaska 'turtle season' as July through October with 75% of occurrences during this four-month period.

Historically, marine turtle occurrences in the high latitudes of the North Pacific Ocean have been associated with warm-water years (Eckert 1993). However, in Alaska *Dermochelys* occurrences do not reflect a warm-water year connection, with only 53% of occurrences in warm-water years. *Dermochelys* has occurred in 3 warm-water years (10 occurrences), in four normal-water years (9 occurrences) and none in cool-water years (Fig. 2). Likewise, hard shell turtle (*Chelonia, Caretta, Lepidochelys*) occurrences in Alaska do not reflect a warm-water year connection, with only 47% of occurrences in warm-water years. Hard shell turtles were recorded in two warm-water years (7 occurrences), in five normal-water years (8 occurrences) and none in cool-water years (Fig. 2).

The State of Alaska is 3840 km east (Hyder, 55°54.7'N, 130°01.3'W) to west (Attu Island, 52°55'N, 172°57'E) (Fig. 1). Hyder is in the northeastern Pacific Ocean; Attu Island is in the northwestern Pacific Ocean, west of the international date line. Amatignak Island (51°17'N, 179°08'W) in the Aleutian Islands is the southernmost point in Alaska. Alaska has 10,624 km of coastline and 54,246 km of shoreline (including islands). Because of low human population throughout most of the coastal area, chances for human-turtle contact are minimal. Much of the coastline, especially Southeast Alaska (south of 59°N and east of

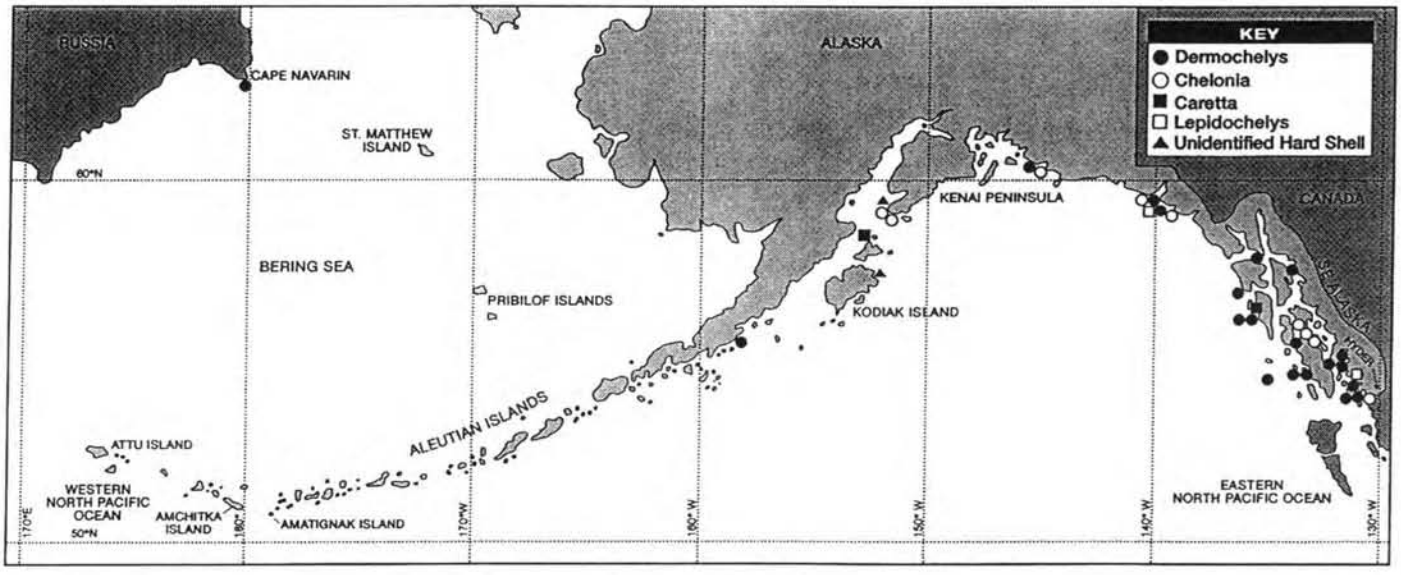

FIG. 1. Marine turtle occurrences in Alaska waters.

137'W) and the Aleutian Islands, is not readily accessible to beach combing. We suspect most cold-killed, grounded turtles are probably destroyed by wave action (pounding on rocks) and scavengers before anyone finds the evidence. Consequently, all reported Alaska marine turtle occurrences are in clusters near centers of human population; 21 in Southeast Alaska, 5 near Yakutat, 2 near Cordova, 3 near Homer on the lower Kenai Peninsula, 2 in the Kodiak Island group and 1 at Perryville on the Alaska Peninsula (Fig. 1).

Dermochelys was first recorded from British Columbia in August 1931 (MacAskie and Forrester 1962) but not recorded from Alaska until 1963. MacAskie and Forrester (1962) reported 10 observations of *Dermochelys* from British Columbia over a 31-year period (1931–1961) and were impressed the turtles were active at sea surface temperatures near 11.7°C. We have 19 Alaska *Dermochelys* occurrences for a 39-year period (1960–1998) and similarly low sea surface temperatures in September, which average 10.9°C, and range from 9.95°C to 12.28°C (Wing and Pella 1998). *Dermochelys* regularly occurs in cold temperate waters of high latitudes (Bleakney 1965; Pritchard 1980; Eckert et al. 1989). North of 60°N latitude in the northeastern Pacific Ocean, *Dermochelys* has been recorded from the Copper River flats (60°25'N, 145°00'W) near Cordova, Alaska (Hodge 1979). North of 60°N latitude in the Bering Sea *Dermochelys* has been recorded at Cape Navarin, Russia (62°17'N, 179°13'E) (Bannikov et al. 1971). Cape Navarin is 450 km northwest of Saint Matthew Island, Alaska and 1200 km due north of Amchitka Island (Aleutian Islands), Alaska. *Dermochelys* is a cold-tolerant turtle with recorded body temperatures well above ambient water temperatures, heat retention capabilities, and demonstrated endothermy (Ernst and Barbour 1989; Ernst et al. 1994). It is not surprising *Dermochelys* represents 58% of Alaska marine turtle occurrences.

The cold-tolerant *Dermochelys* may respond favorably to the Alaska environment. Late summer sea temperatures are frequently within or above the 15–16°C (Wing and Pella 1998) associated with *Dermochelys* off the California coast (Starbird et al. 1993). Atlantic Ocean *Dermochelys* maintain elevated body temperature (25.5°C) in much colder water (7.5°C) (Frair et al. 1972; Paladino et al. 1990). Estimated mean selected body temperature of *Dermochelys* ranges from 25.5–33°C (Mrosovsky 1980; Spotila and Standora 1985), easily attainable in late summer and early fall Alaska waters. Known or presumed foods of *Dermochelys* are often abundant in the Gulf of Alaska during late summer and fall and are concentrated in the deep scattering layer (e.g., siphonophores) and along thermal fronts (e.g., salps, scyphozan and hydrozoan medusae).

The hard shell turtles that occur in Alaska waters (*Chelonia, Caretta, Lepidochelys*) are considered tropical, subtropical, and warm temperate species that rarely stray into cold waters (Eckert 1993). Most hard shell turtles seek optimal sea water temperature near 18°C and are cold-stressed at sea water temperatures below 10°C (Mrosovsky 1980; Schwartz 1978). North of 60°N latitude in the northeastern Pacific Ocean, *Chelonia mydas* has been recorded from the Copper River flats near Cordova, Alaska (Table 1). This is the northernmost Pacific Ocean record to date. Although four *Chelonia* have been observed alive in Alaska as late as October, they probably could not survive to return to warmer waters. Two occurrences of live *Chelonia* (October–November 1976 and

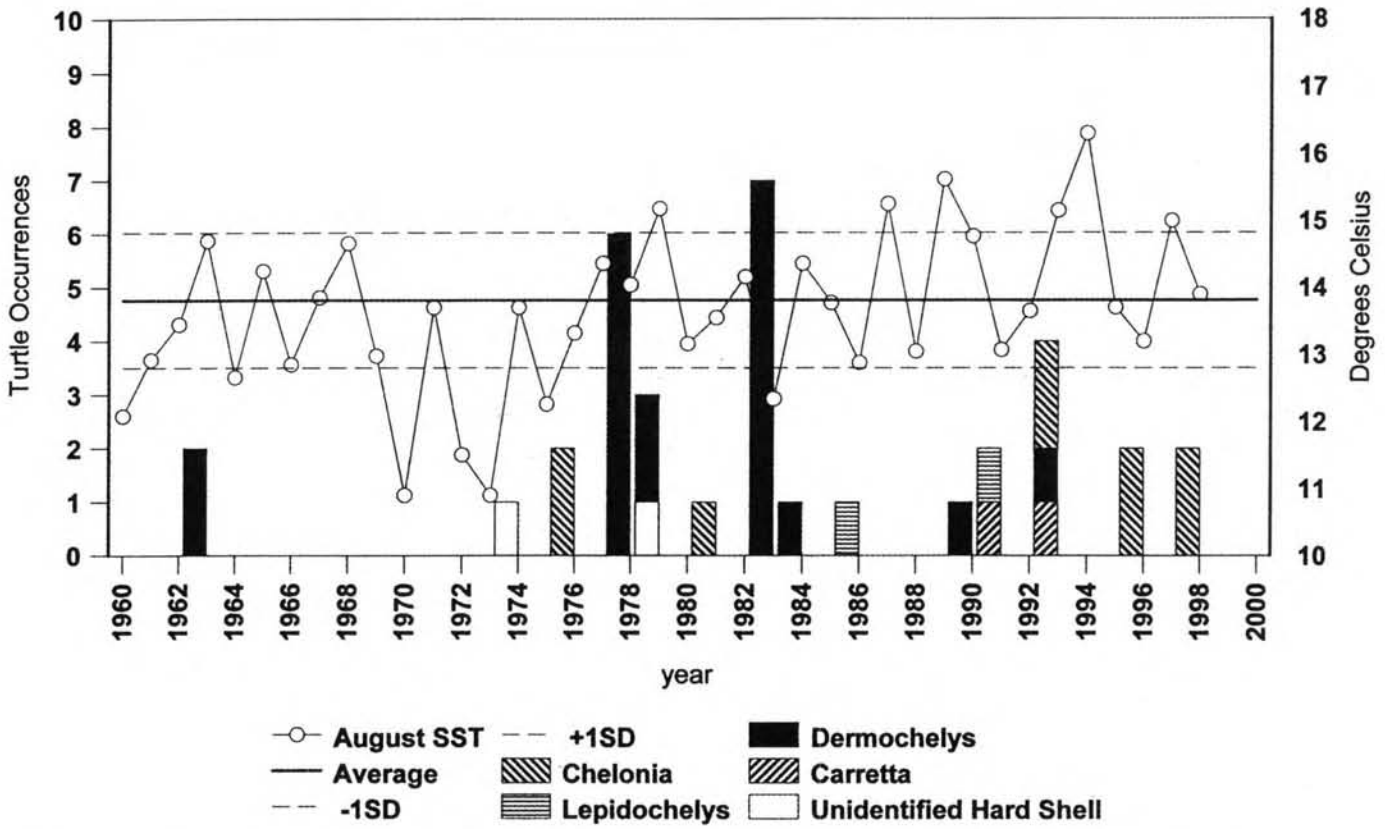

FIG. 2. Annual distribution of marine turtle occurrences in Alaska waters and annual variation of August sea surface temperatures at Auke Bay, Alaska.

October 1993) are believed to be individuals later found and reported as carcasses (Table 1). The *Chelonia* captured October 1996, near Cordova, Alaska, was obviously cold-stressed and transported to Sea World Aquarium, San Diego, California, for rehabilitation. This turtle did recover and subsequently was tagged and released off southern California (Hubbs-Sea World 1998).

Marine turtles are a natural part of the Alaska marine environment, although they are uncommon in the northeast Pacific Ocean north of Oregon (Stinson 1984). Marine turtles occur in Alaska waters too frequently to be considered 'accidental' as defined in ornithological literature. The occurrence terminology developed for Alaska birds by Isleib and Kessel (1973) and referenced by Armstrong (1990) appears to apply equally well to Alaska marine turtle occurrences and marine turtle occurrences generally. Using this terminology, *Dermochelys* are uncommon, *Chelonia* rare, and *Caretta* and *Lepidochelys* casual visitors to Alaska waters. The low frequency of occurrence of hard shell turtles in Alaska indicates they are straying beyond their tolerable range. The higher frequency of occurrence of *Dermochelys* suggests they are ranging into marginal habitat that may not be consistently used from year to year.

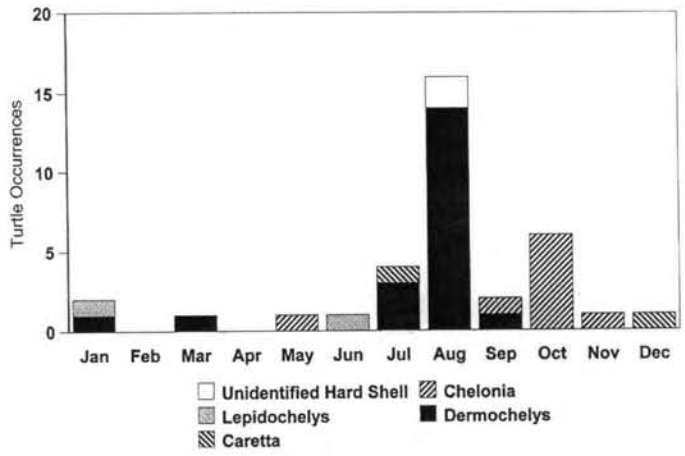

FIG. 3. Seasonal distribution of marine turtle occurrences in Alaska waters.

Acknowledgments.—George Balazs, Richard Carlson, Peter Dutton, Michael Murphy, and Dennis Russell gave valuable and considerate reviews.

Maternal Care and Infanticide in the Australian Skink, *Egernia stokesii*

ELVIRA J. LANHAM
and
C. MICHAEL BULL
Biological Sciences, Flinders University of South Australia
GPO Box 2100, Adelaide 5001, South Australia, Australia
e-mail (EJL): elvira.lanham@flinders.edu.au

Maternal care is often reported among mammal, bird, and crocodilian taxa. It also occurs less commonly among oviparous squamates, usually in the form of attendance of eggs by the female (Shine 1988). It is, however, rare among viviparous lizards (but see Niekisch 1975 and Halloy and Halloy 1997 for exceptions). Maternal care in viviparous species includes female defense of a home range that also contains neonates (Halloy and Halloy 1997), and increased female aggression to the approach of humans after the birth of her offspring (e.g., *Tiliqua nigrolutea*; A. Edwards, pers. comm).

Some species of mammals and birds exhibit both maternal care and, rarely, maternal infanticide. Many reptiles and amphibians exhibit a form of infanticide—oophagy—where a female consumes her own eggs for nutrition or to remove dead or decaying eggs and thus enhance survivorship of the remaining clutch (Mitchell and Groves 1993). However, most reports of consumption of live young involve adults devouring unrelated neonates. Maternal infanticide, where a female consumes her own live young, is still considered rare (Jenssen et al. 1989).

Maternal infanticide may be advantageous if it results in reduced competition for limited resources either for the adult or for its remaining offspring, if it provides otherwise unavailable energy resources, or if it improves inclusive fitness of parents by selective killing of deficient offspring (Huntingford and Turner 1987).

In this note we report maternal care and infanticide in the Australian skink, *Egernia stokesii*. This medium-sized lizard (average adult SVL = 19 cm) occupies crevices in rocky outcrops throughout central and southern Australia. It forms stable aggregations of up to seventeen individuals. One adult of each sex and their offspring share several crevices within highly overlapping home ranges. These groups remain together both between and within years. Other unrelated adults are also often found in some groups. Juveniles remain in their natal group for up to five years (G. Duffield, pers. comm).

Eleven gravid females, collected in January 1996 from several sites in South Australia, were held in glass tanks (35.5 x 30 x 60 cm) with shelter, water ad libitum, and food twice weekly. Live young were born in February and early March 1996. Births in two litters were video recorded on 25 February 1996 in tanks with shelters removed (but with the glass sides covered with paper to minimize disturbance and awareness of lizards in other tanks). Seven births, four from Female 1 and three from Female 2, were recorded over 6.5 h, beginning at 1340 h. Before parturition, contractions, shown by a lateral movement of the tail, lasted up to 40

min. Neonates were fully emerged and moving within 10 s of the appearance of the head.

Infanticide.—Female 1 produced one young at 1340 h, a second at 1600 h, and a third 2.5 min later. On the video playback, the third neonate appeared no different from the first two. It was moving 13 s after birth, similar to the first two neonates, and it seemed fully formed in all respects. The mother appeared to still be having contractions until she approached the newborn 100 s after birth, grasped it in her mouth, struggled with it for 75 seconds during which time it was still alive, and had consumed it completely within a further 32 s. In the next minute, the female approached one of her other neonates, "nosed" it, then lay still in the corner of the tank for 90 min before producing a fourth neonate. The mother showed no signs of aggression toward this juvenile, and produced four additional live young (unrecorded) in the next 20 h.

Without direct observation of each birth, it is difficult to estimate the frequency of maternal infanticide. Egg sacs are quickly consumed by neonates or their mother, removing any possible evidence of such occurrences. Unexplained disappearances of neonates have occurred, but normally these tanks have contained both parents, so even if infanticide is assumed it is impossible to determine which parent was involved. Anyway, these cases differ from the one just described, because they have occurred hours or even days after birth.

Maternal assistance.—The video playback showed that Female 2 produced two young in the period 1400–1800 h. The mother began further contractions at 1840 h and produced a third young at 1903 h. After 15 s the baby was still in the embryonic sac and had not moved. A minute after birth, the baby began to move, but seemed unable to free itself from the sac. The mother began to touch the baby with her snout after a further 30 s, and 10 s later she began to chew on the membrane. After another 20 s (and two minutes after parturition) the neonate was free from the sac and moving around. For two more minutes both mother and baby appeared to be eating the remains of the embryonic sac. The mother had nosed the area where the embryonic sacs had been for the first two births, but had not actively attempted to eat them while those young were still inside. These first two neonates emerged quickly (< 10 s) from their embryonic sacs and then ate the sacs themselves. Female 2 produced an additional three offspring (unrecorded) in the next 24 h.

Maternal infanticide may be advantageous if the offspring is unlikely to survive because it is deficient or deformed, and the mother can gain greater nutritional value from consuming it before it dies naturally (Huntingford and Turner 1987). In this case, the birth video record showed no obvious problem. Selective killing of some young to reduce competition for resources among survivors seems an unlikely explanation, because subsequent offspring were not killed. Stress due to captivity is another possible cause of the infanticide, although it is unclear why the female behaved aggressively to only one offspring.

This report suggests infanticide can occur in litters of *E. stokesii*. Since most births were unrecorded, we cannot comment on the frequency of infanticide among the other nine captive females, nor do we know if this behavior occurs in field populations.

Similarly, we cannot report on the frequency of mothers giving assistance to young in emerging from the embryonic sac, as observed in the second female. If the mother is only trying to derive nourishment, she would be expected to attempt to eat more embryonic sacs. It is more likely that the mother is providing assistance for those juveniles that cannot emerge from the sac without help.

Closely related species exhibit both similar and completely contrary behavior. *Egernia cunninghami* will bite through the umbilical cord if the neonate cannot free itself, but unlike *E. stokesii*, the female will wait for up to 15 min before intervening (Niekisch 1975). Conversely, *Tiliqua nigrolutea* will allow its offspring to die of exposure rather than assist them with removal of the embryonic sac (A. Edwards, pers. comm.).

Acknowledgments.—We thank the Flinders University Animal Care Unit for caring for the lizards in this study and Juergen Stein for additional information about births.

Field Biologist Positions Available

Three paid positions and two volunteer positions for a herpetological survey of northeastern Colorado are available. There is also the possibility of conducting this work as part of a Master's program at UNC. One position is available immediately, two additional positions available 1 July 2001; all positions are contingent on continued funding. Survey is projected to run April-October, 2000-2002; schedule will be 10 days on/four off. Applicants must be able to conduct fieldwork in difficult arid conditions (shortgrass prairie) with minimal supervision. Previous experience with fieldwork and a familiarity with rattlesnakes are helpful and preferred, as are diplomatic communication skills. For further information and initial consideration, please contact Dr. Stephen P. Mackessy at spmacke@bentley.unco.edu. Applicants will be required to submit a letter of qualifications, intention and experience, and two letters of recommendation, to: *Dr. Stephen P. Mackessy, Department of Biological Sciences, University of Northern Colorado, CB 92, 501 20th Street, Greeley, Colorado 80639-0017, USA.*

Xenosaurus platyceps is a poorly studied lizard found in the central part of the Mexican state of Tamaulipas. Recently there have been some reports about female reproduction (Ballinger et al., in press); prey chemical discrimination (Cooper et al. 1998); antipredatory behavior (Cooper et al., in press); and natural history (Lemos-Espinal et al. 1997) of this crevice-dwelling lizard. However, nothing is known about the size of neonates at birth, or the sex ratio of litters of this viviparous lizard. The purpose of this report is to document those characteristics in *X. platyceps*.

On 7 February 1998 we collected four adult female (106–120 mm SVL; 20.3–25.8 g BM), and two male (120 and 125 mm SVL; 19.6 and 28.0 g BM) *X. platyceps* at km 154.0 on Mexican highway 101 (Jaumave–Cd. Victoria), Municipio de Cd. Victoria (1210 m elevation). Lizards were transported to Laboratorio de Herpetologia - Vivario of Escuela Nacional de Estudios Profesionales Iztacala - UNAM, and housed individually in 51 x 26 x 26 cm glass terraria, each one containing a water bowl, peat moss substrate, and small rocks arranged to simulate rock crevices. Lizards were fed crickets, king meal worms, and wax worms every other day. Room temperature was maintained at 25°C, which is near the mean body temperature in nature (Lemos-Espinal et al. 1997). We also provided a light cycle of 12L:12D.

Three of the four captive females gave birth in June 1998 (average litter size = 2.6 ± 0.66; Table 1), the remaining female laid two large undeveloped eggs in the same month. All neonates were born with yolk sacs that were completely absorbed within 8.5 h of birth. Data on litter size presented here fall in the range reported by Ballinger et al. (in press) for *X. platyceps* (range = 2–4). In addition, all four females were gravid when captured, suggesting that *X. platyceps* from this population may reproduce every year, as reported by Ballinger et al. (in press). Parturition occurred in the same period as reported for populations of *Xenosaurus newmanorum* at Xilitla, San Luis Potosí, and *Xenosaurus grandis* at Cuautlapán, Veracruz. Mating should, therefore, occur in August–September as it does in these other *Xenosaurus* species (Ballinger et al., in press). Of the eight neonates, four were females and four were males, suggesting a sex ratio in nature of 1:1 although larger samples are needed to confirm this pattern. Neonates size varied from 46.0 to 55.0 mm SVL, similar to minimum sizes of individuals collected in the field (53.0 mm SVL, 31 March 1996; 50.0 mm SVL, 8 August 1996; Lemos-Espinal, pers. obs.).

Acknowledgments.—We thank Geoffrey R. Smith and Daniel D. Beck for their helpful comments on the manuscript.

TABLE 1. Comparison of parent-female and neonate data of three litters of *Xenosaurus platyceps* from km 154, Mex-Hwy 101 (Jaumave-Cd. Victoria), Tamaulipas.

Female SVL and BM, before and after parturition	Neonate SVL (Mean ± SE)	Neonate BM (Mean ± SE)	Parturition date
120.0 mm 32.2 g 24.14 g	50.5 ± 0.289 mm N = 4 (2M + 2F)	2.312 ± 0.037 g	15 June 1998
112.0 mm 25.9 g 21.1 g	47.5 ± 1.5 mm N = 2 (1M + 1F)	1.740 ± 0.560	22 June 1998
110.0 mm 30.5 g 25.9 g	54.5 ± 0.5 mm N = 2 (1M + 1F)	1.475 ± 0.325	26 June 1998

Marking techniques must be chosen carefully according to the main purpose of the study, the effectiveness of the technique, the ease of application, and the effect on behavior or survival of the animal (Donnelly et al. 1994). The most commonly used marking technique for adult anurans is toe-clipping. Yet, toe-clipping may result in decreased survival (Clark 1972; Golay and Durrer 1994; van Gelder and Strijbosch 1996) and might interfere with locomotor performance. Another disadvantage is the regeneration of toes, which makes this technique unsuitable for long term studies. Other marking techniques such as Panjet dye marking and Passive Integrated Transponder (PIT) tags had no detected effect on survival or growth, but Indian ink Panjet marks are known to fade within 20 days (Brown 1997), whereas PIT tags are expensive and are often lost (Schooley et al. 1993). The most promising method so far is a pressurized fluorescent marking technique, but it is still expensive, heavy to transport into the field, and the application is potentially harmful to small anurans (Schlaepfer 1998). No references for use in adult amphibians are available. Although other micro-tagging techniques have been successfully used in fishes, such as Coded Wire Tag (1.1 mm x 0.25 mm stainless steel wire; Mattson et al. 1990; McMahon et al. 1996), and Visible Implant Alphanumeric Tags (small, 1.0 x 2.5 mm biocompatible implants with an alphanumeric code; Buckley et al. 1994; Frenette and Bryant 1996; McMahon et al. 1996), references to their application in adult amphibians are lacking.

We report here on the use of Visible Implant Fluorescent Elastomer (VIE) tags to mark amphibians. These tags consist of a biocompatible elastomer (Northwest Marine Technology Inc., http://www.nmt-inc.com) which has been successfully used for marking fish (Bonneau et al. 1995; Emata and Marte 1992; Willis and Babcock 1998) and anuran tadpoles (Anholt et al. 1998). The tagging material consists of two components, a liquid elastomer material and a curing agent, which are mixed prior to injection. After injection, the mixture cures into a pliable solid within a few hours at room temperature. Once mixed, the elastomer can be stored as a liquid in the freezer for two to three weeks prior to injection.

We used this technique to mark 40 adult *Rana esculenta*. The animals were anesthetized using a solution of MS-222 (3-aminobenzoic acid ethyl ester) in a 0.5 g/L concentration (Bonath 1977; Green 1979). The fluorescent mixture was injected into the transparent skin between two toes using a 3/10cc insulin syringe. After marking, the animals were placed in fresh water for 20 minutes to allow recovery, after which they were released in their terrarium. The next day all markings were found to be clearly visible under UV-light (Fig. 1). After four months, retention of the marks was still 100%, although some of them decreased in size as much as 20%. At eight months post-injection, the marks had not changed any further.

FIG 1. The VIE tag becomes highly visible under ultraviolet light.

Effects on survival in the field have not been reported. Yet, Govindarajulu and Anholt (pers. comm.) marked 100 *Rana catesbeiana* metamorphs and adults without incident. They recaptured adults in subsequent years with no evidence of mark deterioration. Consequently, VIE tags may be an effective technique for marking anurans because of the low costs (US $240/4000 marks; UV-light $35), the ease and swiftness of application (it takes about one minute, after anesthesia), the high rate of retention, and the possibility of marking many individuals. Because each foot has five webbed toes, this gives a total of eight locations for tag placement. Because the tags are available in four fluorescent colors, a high number of individuals can potentially be marked. Theoretically, with 'no mark' used as part of the marking system, $5^8-1 = 390{,}624$ possible combinations can be made when all eight locations are used. If exactly two tags are put on each individual,

448 unique marks are obtained. In species with webbed front legs, an additional six marking places are available. Other promising advantages, especially for use in the field, are the visibility at night (after recapture and using a UV-source) and the low volume and weight of the equipment.

Acknowledgments.—This study is supported by a GOA-BOF UA 1999 grant to PA. We thank Martin Schlaepfer and Brad Anholt for their useful comments on the manuscript.

Estimating the Number of *Varanus* Inhabiting an Australian Tropical Beach from Track Characteristics

SEAN J. BLAMIRES*
Faculty of Science, Northern Territory University
Darwin, Northern Territory, 0909, Australia
e-mail: s_blamires@hotmail.com

**Present address: The Morning Bell Language School, 671-3 Juk-Do2 Dong, Buk-Gu, Pohang City, Gyeong-Buk, 791-052, South Korea*

Estimating animal populations involves capturing and marking a large portion of the population and then releasing and recapturing a significant proportion of those marked (Nichols 1992). Populations of animals that are difficult to encounter often cannot be estimated (Nichols 1992). Few population estimates have ever been made for monitor lizards (*Varanus* spp.). This is probably because they are difficult to encounter owing to their large size and their wide-ranging, non-social, and secretive habits (Greer 1989; King and Green 1993; Stamps 1977).

Populations of wild cats have been estimated by identifying individuals from measuring track characteristics, such as paw length and width, and toe spread and angle, and clustering the like characteristics (Riordan 1998; Van Dyke et al. 1985). Monitor lizards leave distinctive tracks on sandy substrates when walking in their regular motion from which inferences about their biology can be made (King and Green 1993; Pianka 1994). These tracks are recognizable by a curving line, formed by the side to side motion of the tail imprinting in the sand, and foot prints, imprinted either side of the tail line (King and Green 1993). It may be possible to

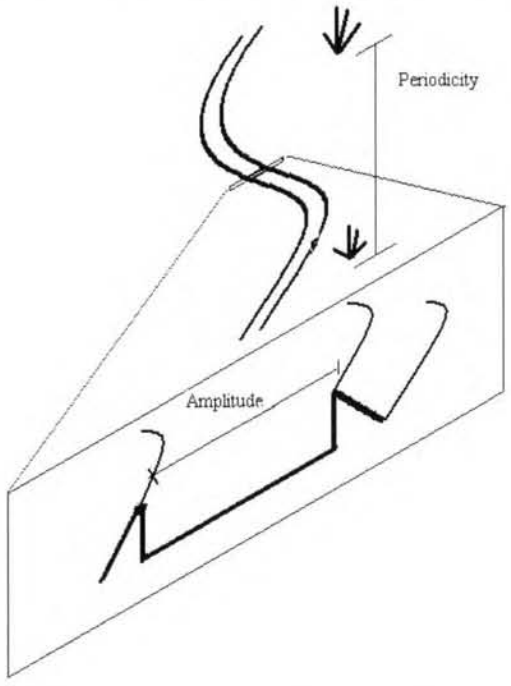

FIG. 1. Measurement taken to estimate the amplitude, periodicity, and foot length of monitor tracks encountered.

TABLE 1. Summary of likely beach inhabited, tail width, stride length and foot length of individual track characteristics derived from *k*-means cluster analysis.

Variable Track	Beach	Amplitude (cm)	Periodicity (cm)	Foot Length (cm)

41	3	3.3	52.3	11.3

estimate the population of sand dwelling monitors by measuring certain track characteristics and clustering those that are alike. In a recent study I used tail width (amplitude), stride length (periodicity), foot length, and region (beach) to estimate the population of *Varanus* inhabiting a beachfront in tropical northern Australia over a two-year period.

The study site was a 5 km stretch of beach, at Fog Bay (12°43'S; 130°20'E to 12°40'S; 130°21'E), approximately 150 km southwest of Darwin, Northern Territory, Australia. The sand dunes lining the beach run parallel to the water's edge, vary in height from one to 13 m, and are set back approximately 35 m from the water's edge. The entire stretch of beach is divided into four smaller

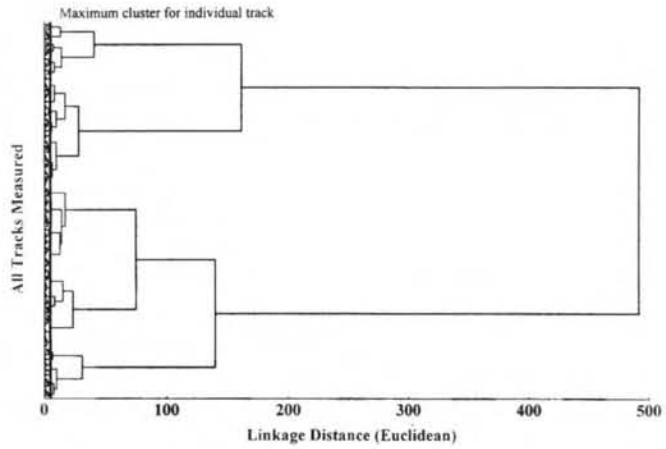

FIG. 2. Hieratical cluster analysis to differentiate individuals from track characteristics (amplitude, periodicity, and foot length). A Ward's (1963) minimum sum of squares linking criteria was used. Line representing the 95% separation point (maximum clustering for an individual) is indicated.

beaches, labelled beach 1 to 4, each of which is approximately 1.2 km long (Blamires and Guinea 1998). During a two-year extensive study of the area, the only monitor lizard species ever observed at the site was *Varanus panoptes* (Blamires 1999); therefore all the preceding measurements were assumed to be of this species.

The area was visited every two weeks for two to seven days over a two-year period. On each trip, all four beaches were walked at sunrise and sunset in order to view tracks when they were most visible (Pianka 1994). Each beach was walked approximately 200 times over two years. Each beach took approximately 0.5 h to walk.

Three measurements were made: amplitude, periodicity, and foot length. Monitor lizard tracks leave a sinusoidal imprint in the sand. Amplitude was measured as the width of the imprint (Fig. 1). Periodicity was the length of stride made by the hind feet and was measured as the straight distance between the heels of the hind footprints on the right side of the tail impression (Fig. 1). Foot length was measured from foot impressions, as the distance from the tip of the furthest claw to the base of the heel (Fig. 1). Foreprints were not measured, as they were usually covered by the hind foot print or the tail drag mark. Every track encountered on each beach was measured to the nearest 0.1 cm with a flexible metal measuring tape. Ten footprints per track were measured and an average taken. All measurements were taken on tracks on the beach scarp. The beach (1, 2, 3, or 4) each track was observed on was recorded. After measuring, each track was raked clear to ensure it was not recounted on subsequent visits. It was assumed that monitors on beaches 1 and 2, and 3 and 4 were isolated, since a creek divides beaches 2 and 3 and there was no evidence from tracks that any monitors crossed the creek.

A hierarchical cluster (Everitt 1980) was used to link like characteristics. Measurements taken for amplitude, periodicity, foot size, and beach were linked by a minimal sum of squares clustering criteria (Ward 1963). The number of branches in the cluster at 95% separation was assumed to equal the number of individual monitor tracks measured (Fig. 2). A *k*-means cluster analysis (Seber 1984) was used to determine the likely amplitude, periodicity, foot length, and the beach for individual monitors.

A total of 172 tracks were measured over the study period. From the cluster analysis, I estimated these represented the tracks of a minimum of 41 individual monitors. Amplitude, periodicity, foot length, and beach for individual tracks are shown in Table 1. Amplitude was positively correlated with periodicity (r = 0.343; P = 0.028) and foot length (r = 0.387; P = 0.013), and periodicity was positively correlated with foot length (r = 0.437; P = 0.004; Fig. 3).

Potential difficulties occur if individual lizards alter tail posture during running or certain displays (Green and King 1993) and change movement posture in response to a sloping terrain (Reichman and Aitchison 1981). Therefore, multiple measurements must be taken on numerous tracks, ensuring a consistent slope. I made no measurements of tracks that traversed the dunes. The population at Fog Bay may be overestimated due to the same individual's tracks having the same amplitude but different periodicity when re-encountered due to running or display. Accordingly, if any tracks with the same mean amplitude occur on the same beach they may be regarded as belonging to the same individual. Thus, there may be as few as 28 individuals inhabiting the area. From Table 1; tracks 1 and 2; 6 and 7; 4 and 12; 15 and 41; 5 and 16; 19 and 24; 23 and 27; 22 and 29; 26 and 30; 3 and 38; 35 and 39 and 28, 33 and 40 may be the same individual.

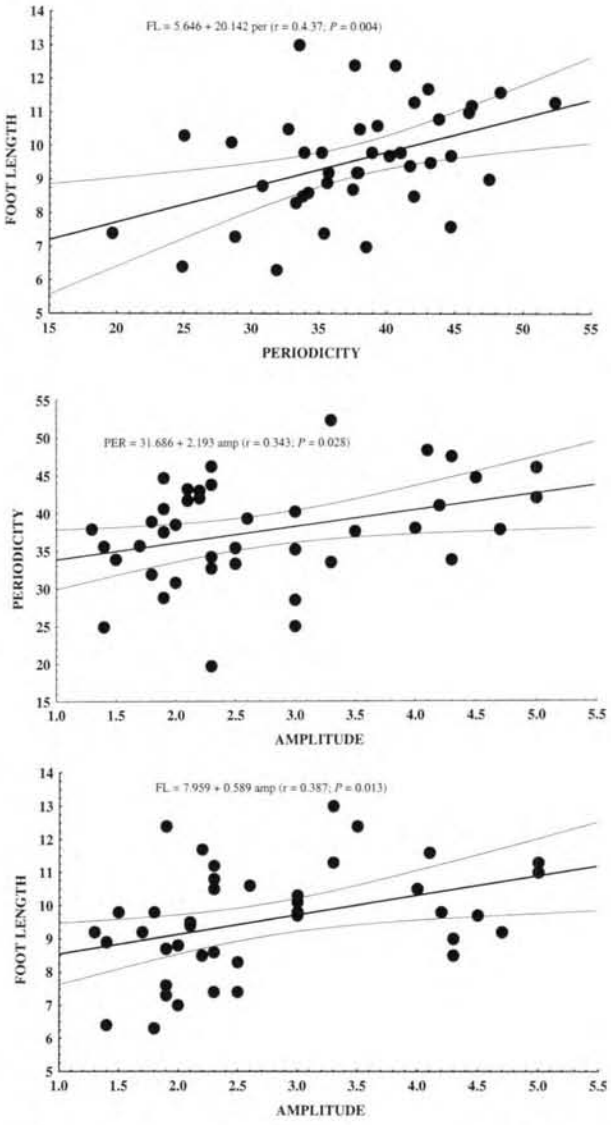

FIG. 3. Correlation plots and equations for associations between amplitude, periodicity and foot length.

Recognition of individual monitors from tracks on a sandy substrate, may prove useful in ways other than estimating the population, for example it may relieve the need to capture and release, or radio track individual monitors to estimate activity area. A database with track characteristics of individuals in an area may be created. Each individual's tracks can then be readily recognized by measuring the characteristics of any tracks left in the substrate. Each individual's movements may be determined by following its track. Furthermore, burrow sites of individuals may be determined, and by collecting and analyzing the contents of scats associated with an individual's track, the diet of each individual could be determined.

Following the tracks of sand-dwelling monitors has been used to determine foraging paths and daily distances moved for different species of *Varanus* (Pianka 1986, 1994). However, by taking further measurements additional knowledge may be gained about the habits of sand-dwelling monitors. This should reduce the need to locate individual lizards and eliminates any behavioral changes that might be caused from applying tags.

Effectiveness of Three Trap Types in Drift Fence Surveys

JAMES L. CHRISTIANSEN*
Department of Biology, Drake University
Des Moines, Iowa 50311, USA
e-mail: James.Christiansen@drake.edu

and
TERRY VANDEWALLE
Earth Tech, 501 Sycamore Street, Suite 220
Waterloo, Iowa 50703, USA
e-mail: Terry_Vandewalle@earthtech.com

We frequently use drift fences along with other techniques to monitor terrestrial movements of turtles and other small animals in Iowa. Through the 1970s and early 1980s we used pitfall traps straddled by a drift fence as our primary terrestrial sampling method. Our observation of terrestrial turtles going great distances to avoid entering a pitfall trap caused us to seek alternatives. Iverson (1991) field-tested a funnel (box) trap, a rectangular version of his aquatic trap (Iverson, 1979) and sent us a sample to copy. This new device was initially much more effective for collecting terrestrial turtles than were our pitfall traps. However, we frequently observed turtles walking around wire box traps just as they had

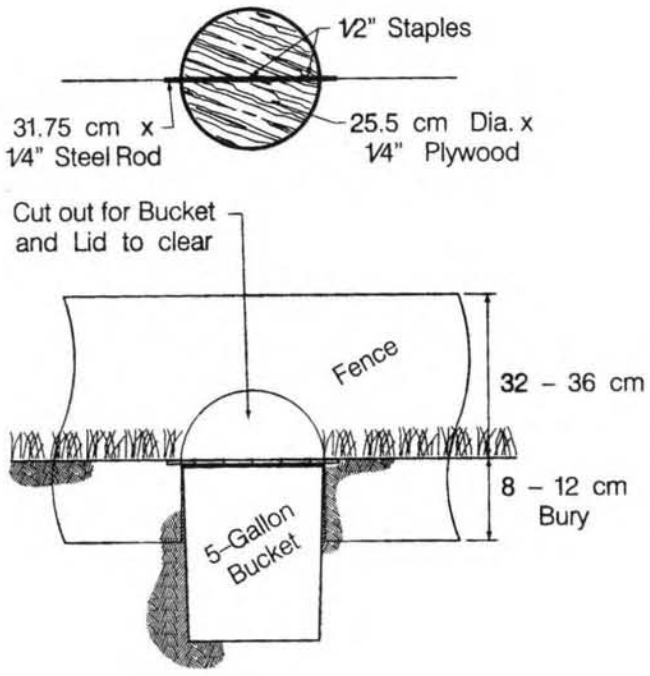

FIG. 1. Specifications of flip-top lid on 19-liter (5-gallon) bucket set in drift fence.

FIG. 2. Flip-top lid on 19-liter (5–gallon) bucket with basking *Cnemidophorus*. All traps tested were set in openings in the drift fence similar to the one shown.

our pitfall traps, especially after several recaptures. As a result, we began experimenting with other types of drift fence trap. This paper compares the effectiveness of open 19 liter (5-gallon) pitfall traps, Iverson's wire box traps set in the fence line rather than along the fence, and our final design of a flip-top lid 19 liter pitfall trap. It examines effectiveness in capturing a variety of turtles, lizards, amphibians, and a few small mammals and discusses our earlier designs for covered pitfall traps and our reasoning for selecting the design we now use.

Because turtles, especially adults of terrestrial forms such as *Terrapene ornata* and *Kinosternon flavescens*, usually walked around the open pit presented by an uncovered 19-liter pitfall trap, it appeared to be almost as effective a barrier as the drift fence. Because of our need to sample species that do not freely enter pitfall traps and can not be trapped effectively by wire box traps, we tried to develop a trap that was effective for turtles and reasonably effective for other species.

Our first attempt was to use pitfalls of a variety of sizes, 3.8–19 liter (1–5 gallon) covered with star-cut plastic of several different grades of thickness. The soft plastic top was spray painted the color of the sandy environment and fastened to wooden crochet rings that were slightly larger than the opening to the pitfall. The intent was to have a surface that was level with and the same consistency and color as the surrounding soil. The flaps of cut plastic were intended to bend downward as the animal reached the middle and to return to their original position when the animal fell through into the pitfall. Although we conducted numerous trials, we were unable to find a plastic with enough elasticity to return to the original position, especially in the hot sun, and enough flexibility to dump an animal even as heavy as a small turtle, into the trap. We rejected this design and began experiments with flip-top lids.

Our first 19-liter pitfalls with flip-top lids had circular, brown plastic tops supported by plastic rods that were glued to the top across the center of the circle with about 2.5 cm of rod projecting from each side. The lid was then fitted into two holes drilled in opposite sides of the pitfall bucket. While somewhat effective, we found that sand became wedged between the rod and the plastic of

TABLE 1. Number of captures (% of total) at the Big Sand Mound preserve for 5620 trap nights and chi-square values for open 19-liter (5-gallon), flip-top lid (covered) 19-liter, and wire box traps set along drift fences at Big Sand Mound in 1995 and 1997. Significance of difference from expected values among all three traps *=$p<.05$; **$p<.01$; *** = traps that were significantly more effective than the next best trap ($p<.05$) when Chi^2 was rerun comparing the two best traps.

the pitfall making it difficult for the lid to flip (rotate down, dumping the animal) and to return to its original position. In addition, the solar-heated glue tended to melt, allowing the lid to separate from the rod, and the plastic rod polymerized and easily broke.

These problems were corrected by using wooden tops supported by metal rods and by cutting grooves in the opposite sides of the pitfall bucket instead of drilling holes. We experimented with various designs in the early 1990s and produced our final design in 1995 (Fig. 1). The nearly circular lid was made of 6.5 mm (1/4 inch) plywood with a 31.8 cm metal rod stapled along the maximum diameter. Slight variations in lid diameter allowed the lid to rotate freely in buckets of slightly different size leaving a 7 mm space between lid and bucket wall (Fig. 2). Notches cut into the tops of the buckets allowed the rod to rotate without the binding that occurred with drilled holes. The rod was placed in line with the fence and an opening was cut in the fence to allow the lid to rotate and to tempt the animal to try to pass through the fence at that point (Fig 2).

We began testing our final design in April 1995 at Big Sand Mound, a large relict sand prairie just south of Muscatine, Iowa. Approximately 1500 m of drift fence was constructed along several pools at that site. The traps were spaced about 8 m apart with the flip-top lid pitfalls alternating with wire box traps set across openings in the fence, and open 19-liter pitfalls also set in openings in the fence, so that every 24 m had each trap type represented. Capture results based on 5620 trap nights at Big Sand Mound are shown in Table 1. Table 2 shows a comparison of a similar set of drift fences, but without the wire box traps, for 2062 trap nights at Eddyville dunes, a sand prairie in Wapello Co., south-central Iowa in spring 1997. Our traps were normally sampled four times each day at approximately 0800h, 1000h, 1700h, and 1900h.

Our tests confirmed Iverson's observation that wire box traps were more effective than open pitfalls in catching adult *Kinosternon flavescens* and *Terrapene ornata* although his traps were set along the two sides of the fence while ours were set in openings in the fence, making comparisons less precise. However, Tables 1 and 2 clearly show that adult turtles *(Terrapene, Chrysemys, Kinosternon)* were much more likely to enter flip-top lid traps than either open 19-liter traps or wire box traps. Hatchling turtles, except *Graptemys pseudogeographica,* were more frequently caught in flip-top lid traps than any other kind but not significantly more. Open pitfalls were more effective in collecting *Graptemys pseudogeographica*

TABLE 2. Number of captures (% of total) at the Eddyville Dunes for 2062 trap nights and chi-square values for open 19-liter (5-gallon) and flip-top lid (covered) 19-liter traps set along drift fences in 1998. Significance of difference from expected values *=$p<.05$; **$p<.01$.

hatchlings, *Cnemidophorus sexlineatus*, *Bufo woodhousii*, *Rana catesbeiana* and *Rana clamitans*. Small mammals were usually more frequently found in open pitfalls than in flip-top lid traps and were almost never found in wire box traps.

We suspect that frogs and toads may be attracted to the open pitfalls by the abundant insects that accumulate there and this could be a feature in attracting lizards as well. *Cnemidophorus* sometimes used the flip-top lids as basking places, tilting the angle of the lid appropriately into the early morning sun (Fig. 2). The biases introduced by trap type should be considered along with the biases created by drift fences and proximity to other structures reviewed by Dodd (1991), Corn (1994), and Brown (1997). The results of this study suggest that flip-top 19-liter pitfall traps are much more effective in capturing adult terrestrial turtles than are either wire box traps or open pitfalls. Open pitfalls were more effective at capturing amphibians, lizards, and small mammals. Because of these observations, we suggest that a combination of open pitfalls and flip-top lid pitfalls be used in studies intended to sample reptile and amphibian species richness. Box traps set on the two sides of the fence need to be tested to determine their effectiveness in comparison to flip-top lid pitfalls.

Acknowledgments.—We thank Robb Goldsberry for help in making the flip-top lids and Steve Maynard for producing the line drawing. We are thankful to Tom Kramer for checking the fence and recording data when we could not be present, and Mid America Energy and the Iowa Department of Transportation for funding the studies for which these experiments were peripheral. We thank Rod Ridnour and his crew for help in constructing the Eddyville drift fences.

The study of animals in the field usually requires their capture and this often can be a challenging part of research. The number of possible techniques for capturing small- to medium-sized lizards continues to grow. "Active traps" include noosing (Strong et al. 1993; Durden et al. 1995), or elastic bands and varied grabbing devices (Bedford et al. 1995; Durtsche 1996; Witz 1996), but some lizards are particularly elusive and difficult to capture by these methods. "Stable traps" include drift fences (Greenberg et al. 1994; Enge 1997), pit traps (Greenberg et al. 1994), glue traps (Bauer and Sadlier 1992; Rodda et al. 1993; Zani and Vitt 1995; Whiting 1998), and wire mesh traps (Doan 1997; Zani and Vitt 1995), but these kinds of traps need to be checked frequently or animals may die in them.

We studied a growing population of European wall lizards (*Podarcis muralis*), introduced near Victoria, British Columbia, Canada. Although we were able to capture most animals with a simple noose, we noticed that some lizards consistently avoided the noose and that other lizards used habitat unsuitable for noosing (e.g., brush and tall grass). To capture these additional lizards, we installed pit traps around the habitat. These traps were successful, but we found that predatory animals, such as raccoons, were quick to prey on the trapped lizards. Raccoons were adept at catching the lizards despite partial lids over the traps, frequent checking of traps, and relocation of traps. As well, frequent relocation of traps led to considerable disruption of the habitat area.

To overcome these difficulties, we developed a "habitat trap" for *Podarcis muralis*. We believe that this kind of trap likely also would be effective for catching many other small- to medium-sized lizards and other terrestrial animals. The trap consists of an artificial construct of a preferred habitat, which is placed on a large piece of camouflaged plastic. Once the animals begin to occupy the artificial habitat, the plastic sheet is lifted at all edges and the animals are trapped.

To catch wall lizards, we decided to simulate a rockpile or woodpile, structures in which these animals naturally seek shelter. First, we excavated a shallow pit about 15 cm deep, gradually tapered in depth, with a total area of about 1 m^2. Whether a pit is a required part of the trap is not known, but we thought that it would increase the attractiveness of this artificial habitat to lizards by allowing

them to go deeper, especially at night. A clear plastic sheet was then laid in the shallow pit with a border of plastic approximately 30 cm beyond the excavated area. The edges of the plastic were buried in a shallow layer of soil or surrounding substrate. Then, we placed large cover structures, each approximately 30 cm^3, such as cinder blocks, stones or pieces of wood, centrally on the plastic. We arranged these objects to simulate a natural shelter habitat. Additional cover objects could have been added to assist in camouflaging the plastic and make the habitat structure more attractive to the lizards, but we found this to be unnecessary for wall lizards. Camouflaging the edge of the plastic sheet with cover leaves or grass also must be balanced against the added time of locating captured lizards in the clutter of excess camouflage litter when the edges of the plastic are lifted. For wall lizards, 2–3 days was sufficient time for lizards to be attracted to the trap.

A limiting feature of our trap is that at least two people are needed to lift the plastic and catch the entrapped lizards. We approached the trap from opposing sides, in order to reduce the likelihood of lizards fleeing the trap from a side away from us. This method in fact seemed to encourage the lizards to take refuge inside the shelter habitat, rather than attempting to leave. We then simultaneously lifted the edges of the plastic, while trying to ensure that soil at the perimeter fell to the outside of the plastic. We kept the edges of the plastic raised and rolled it while moving towards the center of the trap. The large stone and wood cover objects, along with any litter, were removed carefully to ensure that lizards were not injured. The trapped and exposed animals could then easily be collected from the bottom of the bowl formed by the plastic sheet. After we had recorded data on the lizards, we returned them to the now reassembled trap. This experience did not seem to have any long-term effect on the lizards and they continued to use the trap after re-assembly. It took about 20 minutes to disassemble the trap, capture the lizards, and then reassemble the trap.

Because we constructed only one trap and terminated the study shortly afterwards, we cannot give any experimental results that test its effectiveness. We used the trap from 15 July–19 August 1992. During this period, we caught 33 individual lizards at the study site, six of which were caught in the trap; one of the six was a recapture from earlier in the study. Repeated sampling at the trap resulted in repeated capture of the same lizards. Thus, it appears that lizards, at least temporarily, adopted the trap as a regular refuge. Because wall lizards do not move around very much (unpublished data), we would have needed to set up traps throughout the study site to sample the population more broadly. Nonetheless, the results of this short trial suggest that this is a feasible approach for studying this species.

The main advantage of this trap is that it allows the animals to live in their "natural" habitat with safe hiding places, without requiring us to check the traps at any particular time. The only cost is the expense of plastic sheeting and the brief period of time required for assembly and sampling. We believe that the habitat trap would be an effective way to catch various kinds of lizards and other terrestrial animals.

In reptiles, prolonged anesthesia is often the frustrating consequence of a relatively slow metabolic rate combined with the use of traditional anesthetics. A drawn out anesthetic procedure is perhaps most problematic in field studies because prompt return of a fully recovered reptile to its habitat minimizes data artifacts which may be generated by stress, anesthesia, fasting, or dehydration. Propofol is a new generation, non-barbiturate, substituted isopropyl phenol anesthetic (Weaver 1990). Its benefits include rapid onset and rapid recovery from anesthesia, short duration of action, safety for use in physiologically compromised animals, lack of significant side effects, and minimal equipment requirements (Sebel and Lowden 1989; Smith et al. 1994). Its main disadvantage is that it must be administered into a blood vessel or bone marrow cavity. Propofol has a very large volume of distribution, which results in a rapid drop of anesthetic blood levels once the drug is discontinued (Biebuyck 1989; Branson and Gross 1994).

As a result, the recovery is rapid and virtually independent of metabolic rate. Several authors have reported useful doses for induction of anesthesia in captive boids, green iguanas, and turtles (Bennett et al. 1998; Divers 1996; Lawton 1992; Pye and Carpenter 1998). Although propofol has been evaluated in snakes under experimental laboratory conditions (Anderson et al. 1999), this is the first study to evaluate the use of propofol as a field anesthetic for the implantation of intracoelomic radio-transmitters in free ranging reptiles.

During November and December 1997, we collected 11 brown treesnakes (*Boiga irregularis*) using traps and visual surveys on the Northwest Fields region of Andersen Air Force Base on the island of Guam. This area consists of typhoon impacted, limestone rain forest interspersed with unused, paved runways. We weighed snakes to the nearest gram with spring scales (0 to 300 g, Pesola™, Pesola, Switzerland) and then prepared a 5 mg/kg dose of propofol, (10 mg/ml, Rapinovet™, Mallinckrodt Veterinary, Inc., Mundelein, Illinois, USA), (Anderson et al. 1999) in a 0.5 ml tuberculin syringe with a 3/8 inch, 27 gauge needle. Based on the history of propofol causing a brief (< 60 sec) apnea (temporary stoppage of breathing) in brown treesnakes (Anderson et al. 1999), we also prepared a 2.0 mg/kg dose of a respiratory stimulant (doxapram HCl, 20 mg/ml, Dopram®-V, Fort Dodge Laboratories, Inc., Fort Dodge, Iowa, USA; Carpenter et al. 1996) to administer if apnea lasting longer than one minute occurred in study snakes. Prior to administration of the anesthetic we recorded baseline respiratory and heart rates.

Although with proper training, propofol is easily administered to most snakes via the tail vein, the small size and fragility of these vessels in brown treesnakes required us to administer the anesthetic into the lumen of the heart. We used a standard cardiopuncture technique to administer the propofol (Jenkins 1996). Cardiopuncture is a relatively risk-free procedure in snakes (Anderson et al. 1999; Jenkins 1996; Johnson et al. 1997; Mader et al. 1985), but proper training and excellent restraint are essential to consistently place the tip of a needle in the lumen of the ventricle and to minimize trauma to the heart. Although the snakes resisted restraint, we did not recognize any additional response by the snakes to the intracardiac injection. All snakes were unconscious with little to no muscle tone within 45 sec of a complete injection. When induction of anesthesia was complete, one person finished the aseptic preparation of the skin for surgery and started the radio-transmitter implantation procedure while another person measured the snake's heart and respiratory rates. Maintenance of surgical anesthesia was monitored by the absence of a pain response (movement, increased heart rate) by the snakes. The length of the radio-transmitter implantation procedure from time of injection to placement of last suture ranged from 10–17 min. Excellent surgical anesthesia was achieved in all snakes for this time period. In addition to documenting induction time and length of procedure, we also recorded presence of apnea, heart rate, time until release, and condition of snake upon release to the wild.

In three out of eleven cases, movement by the snake during injection resulted in some or all of the propofol dose to be administered outside the lumen of the heart. Because propofol enters the blood stream extremely slowly after injection into peripheral tissues, additional doses of propofol were required to induce surgical levels of anesthesia. Supplementary doses of propofol ranged from 2–5 mg/kg. Lower doses were chosen when a decrease in muscle tone or righting ability indicated that a snake had received a part of the initial dose into the lumen of the heart. In other species of snakes, use of the tail vein would minimize the injection difficulties that we experienced.

The heart rate dropped from a baseline average of 93 beats per minute (SE = 2.3) to 76 beats per minute (SE = 2.8) by 1–5 min post-injection. Although this is a statistically significant change (Minitab, 2 sample t-test, $P = 0.0011$; Ramsey and Schafer 1997), the heart rates remained within expected values for anesthetized snakes (Muir and Hubbell 1995). All animals maintained normal perfusion judged from mucous membrane color and intra-operative evaluation of coelomic blood vessels. Although direct effects of propofol cannot be ruled out, the most likely explanation for the decreased heart rate is loss of consciousness and cessation of struggling against restraint. Because pain is associated with increased heart rate, the drop in heart rate is one indication that analgesia (pain relief) was adequate. The heart rate did not change significantly between 5 min after induction of anesthesia (mean = 76 bpm, SE = 2.8) and the end of the surgery (mean = 77, SE = 1.7) (Minitab, 2 sample t-test, $P = 0.88$; Ramsey and Schafer 1997) which suggests that the snakes' cardiovascular status was stable.

In general, propofol-induced apnea is short lived and self-limiting (Anderson et al. 1999; Bennett et al. 1998; Muir and Gadawski 1998). All of the brown treesnakes stopped breathing post-injection of propofol; all but three snakes resumed spontaneous respirations in < 1 min. Although brief apnea associated with propofol anesthesia in captive brown treesnakes did not seriously affect the partial pressure of oxygen of heart blood (Anderson et al. 1999) and is not likely to affect the health of a snake in general (Bennett 1991), we chose to be conservative and administered doxapram HCl intramuscularly to these three snakes after 1 min. Spontaneous respirations resumed within 1 min of receiving doxapram HCl in two of the three snakes. The snake that did not respond to doxapram HCl within 2 min had been particularly difficult to restrain and as a result required a total of four injections of propofol to induce anesthesia. We intubated the snake's trachea with a plastic urinary catheter and administered artificial ventilation at a rate of 1–4 breaths per min for 24 min, after which the snake commenced breathing on its own (Muir and Hubbell 1995). All three snakes recovered uneventfully and were indistinguishable from other snakes at release and during a two week radio-telemetric study that followed.

Twenty to 25 min after injection, seven snakes had righting reflexes and four of these snakes were making active escape attempts. After 2 h, all snakes were conscious and active. We released snakes by untying and placing a cloth bag containing the snake at the original capture site. At release, 2–3.5 h post-injection, most snakes immediately left the bag and some exhibited defensive strikes. As part of the field study, we caught, examined, and weighed these snakes every four days for a total of 12 days. Snakes appeared healthy at these times. No weight losses were noted. At the end of the study, lizard remains were identified in the stomachs of 70% of the snakes. No obvious temporal differences in distances traveled or refugia selected were observed over the 12-day tracking period (Anderson, unpubl.).

It is possible that lingering effects of anesthesia could bias subsequent data collection. The consequences of anesthesia can be

reduced by minimizing the time that an animal is removed from its regular environment and altered from its normal metabolic state. In reptiles, the use of traditional injectable forms of anesthesia (ketamine, barbiturates) at a surgical level often results in recovery times of several hours to days (Bennett 1991) and can cause death. The use of vapor anesthetics such as isoflurane or halothane usually results in shorter recovery times (0.5–4 h), but the open drop technique frequently used in the field allows little control of the concentration of anesthetic vapor administered to a snake. As a consequence, even when researchers follow seemingly similar techniques, small differences in ambient temperature, volume of the induction chamber, snake posture, or sponge material can result in marked changes in anesthetic concentration. Low concentrations are associated with prolonged inductions and high concentrations can be associated with prolonged recoveries or death (Bennett 1991). Precise control of vapor anesthetic concentrations requires vaporizers and pressurized oxygen tanks, which are unwieldy for field use. There are also potential health risks of escaped anesthetic vapors to human workers such as organ damage, spontaneous abortions, and birth defects that need to be considered (Hill et al. 1998). Use of propofol circumvents these problems.

Propofol has several limitations. Its short action time is a disadvantage for procedures lasting longer than 15–20 min. A continuous infusion or multiple venous injections (at lower doses) are required in such cases. Administration of an intravenous injection during a procedure can be challenging even with proper training and experience. The incidence and severity of complications increases as the dose and length of anesthesia are increased (Bennett et al. 1998). Once an animal begins to recover from propofol anesthesia, there is no maintenance of pain relief, so it is not useful for procedures likely to induce prolonged pain without the concurrent use of an analgesic. This characteristic also makes it extremely important to finish painful procedures prior to recovery from anesthesia (Branson and Gross 1994). Induction with propofol followed by vapor anesthesia or vapor anesthesia alone is recommended for prolonged procedures.

The dose of propofol required to induce anesthesia is species dependent. Due to the limited data base available for safe, effective dosages in reptiles, it is imperative to determine this information prior to use in experiments in the field. As an example, a common induction dose of propofol for boids is 10–12 mg/kg (Divers 1996). In pre-study testing of brown treesnakes, this dose resulted in a surgical level of anesthesia lasting 30 min to 2 h, apnea lasting up to 7 min, and return of righting reflex occurring in 2–4 h. Snakes receiving this dose of propofol did not return to a pre-anesthetized state for several hours. In continuing pre-study testing, one brown treesnake receiving a dose commonly used in turtles (15 mg/kg; Divers 1996), became apneic, did not respond to doxapram HCl, and required artificial ventilation for 2 h. Although the magnitude of the difference is not as great, dosage also varies by individual. In general, agitated and obese individuals require a 10–20% increase in propofol dose (Anderson et al. 1999).

Acknowledgments.—We thank the Ohio Cooperative Fish and Wildlife Research Unit of the Biological Resources Division of the United States Geological Survey for financial support; Andersen Air Force Base, and especially H. Hirsh and D. Works, for allowing and facilitating access to the site and K. Allen, M. Doles, S. Kot, M. Ritter, and D. Vice for their help in obtaining snakes for this study. All work was performed with the approval of The Ohio State University animal care and use committees.

Reptiles can be stored in a variety of containers; however, the most convenient and widely used are glass aquaria. Glass aquaria provide adequate housing for small reptiles, but are not very practical options for housing large reptiles because they are heavy and easily broken. Large reptiles are housed in a wide variety of containers. Frequently used cages include custom made wood and glass cages, cattle tanks, plastic terraria, and commercially available cages (Mason et al. 1991). While these certainly provide adequate housing options, they are often cost prohibitive, heavy, and difficult to properly sanitize.

We designed an inexpensive cage for large reptiles (1–5 kg) from materials available at any local hardware and/or department store. The cages consist of modified storage containers, hardware cloth and plastic cable ties. Each cage takes roughly 30 minutes to assemble and costs approximately US $12.00. In addition, the cages are lightweight (ca. 2 kg), very rugged, easily sanitized, and adhere to the general guidelines established for housing reptiles by the National Research Council *(Guide for the Care and Use of Laboratory Animals).*

Large storage containers (Sterilite®, ca. 30 gal) were purchased at a local department store. Two front windows (25 cm long x 15 cm high) were cut into the long side of the container with a utility knife. Instead of one large hole, two smaller holes were cut to lend structural integrity to the wall of the storage container (Fig. 1). Our containers were stored under lab benches in a university animal holding facility. Thus to provide a heat source for the animal, we cut another 20 cm x 20 cm window in the short side of the cage so that a heat lamp could heat and illuminate the cage. Additional windows may be cut into the container if so desired. One might rather cut a 22 cm x 44 cm window in the lid of the container for additional air flow or heating options. Any of these designs allow for sufficient heat and light sources while retaining the ability of the containers to be stacked for storage purposes.

Hardware cloth (grid size 0.65 cm x 0.65 cm) serves as a cover for the windows in the walls of the container. Using tin snips, hardware cloth cutouts were cut to the appropriate window size. The dimensions of the cutouts were one inch larger than each dimension of the window to allow for proper fastening. Holes were drilled around each window at roughly 8 cm intervals so that plastic cable ties could be threaded through the hardware cloth cutout, through a hole in the container wall, and then out through the adjacent hole and hardware cloth. Cable ties were secured with the female end of the tie on the outside of the container to keep any sharp edges away from the animal. Once secured, the ends of the cable ties were clipped.

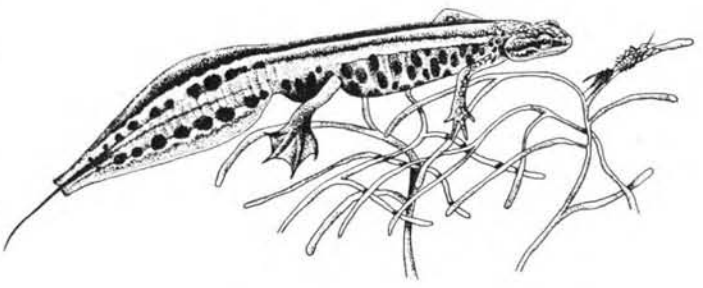

FIG. 1. Inexpensive cage designed to house large reptiles.

The lid of the container snaps to the container body. This alone should be sufficient to secure most 1–2 kg animals. However if additional security is needed for large or active snakes or lizards, two inch binder clips fit the lid and wall of the container well and provide considerable additional fastening strength. We housed large lizards (gold tegus, *Tupinambis teguixin*; savannah monitors, *Varanus exanthematicus*; ca. 1.5 kg, 30+ cm SVL) using two binder clips evenly spaced on each side of the lid. Over a nine month period, no lizards escaped with this arrangement. Thus, these cages proved to provide safe and adequate housing with the added benefits of being lightweight, inexpensive, and easy to sanitize.

Announcing Two New Herpetological Circulars from the Society for the Study of Amphibians and Reptiles

State and Provincial Amphibian and Reptile Publications for the United States and Canada

by John J. Moriarty and Aaron M. Bauer

HERPETOLOGICAL CIRCULAR 28

This new publication provides a complete listing of 818 published articles and books dealing with the herpetofauna at the state and provincial level. The bibliography covers material published from the 1830's up to December 1999. This circular is essential to anyone interested in herpetology and herpetological history at the state or provincial level. iv + 52 pages. ISBN 0–916984–52–4. June 2000

Prices: Prepublication (*SSAR members only*)	After 15 November 2000	US$9.00
first copy: US$8.00 postpaid	**Shipping:** First copy	$2.00
additional copies: $5.00 postpaid	Additional copies	$1.00

Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in our Understanding

by the Joint Committee on Scientific and Standard English Names

Brian I. Crother, Chair

HERPETOLOGICAL CIRCULAR 29

This new list of current scientific and standard English names provides up-to-date taxonomy, with annotations and references, on all species of amphibians and reptiles in the United States and Canada. This list has been adopted as the Official List of the Society for the Study of Amphibians and Reptiles, The Herpetologists' League and the American Society of Ichthyologists and Herpetologists. This publication also provides guidelines on the formation of standard English names and a framework for the creation of future names. Approx. 90 pp. ISBN 0–916984–54. To be published October 2000.

Prices: Prepublication (*SSAR members only*)	After 31 December 2000	US$11.00
first copy: US$10.00 postpaid	**Shipping:** First copy	$2.00
additional copies: $7.00 postpaid	Additional copies	$1.00

SEND ORDERS TO: Dr. Robert D. Aldridge, SSAR Publication Secretary, Department of Biology, Saint Louis University, 3507 Laclede Ave., St. Louis, Missouri 63103 USA. *Telephone* 314-977-3910: *fax* 314-977-3658; *e-mail*: ssar@slu.edu. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MasterCard (Account number and expiration date must be provided). SSAR membership details and a complete list of Society publications can be obtained on request to Dr. Aldridge.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 31, Number 1 (March 2000).

CAUDATA

AMBYSTOMA TIGRINUM (Tiger Salamander) **COCCIDIA.** Although endoparasites from midwestern *Ambystoma* salamanders have been studied (Muzzall and Schinderle 1992. J. Helminth. Soc. Washington 59:201–205; Bolek 1997. J. Helminth. Soc. Wash. 64:292–295; Bolek and Coggins 1998. J. Helminth. Soc. Wash. 65:98–102; Bolek 1998. MS Thesis, Univ. Wisc. Milwaukee. 134 pp.; Yoder 1998. Ph.D. Thesis Univ. Wisconsin, Milwaukee. 138 pp.), no reports exist on their coccidians from this area. Here I report on *Eimeria* spp. from a tiger salamander in Indiana. During the evening of 11 February 1999 a male *Ambystoma tigrinum* (wet weight 30.41 g, SVL 94 mm) was collected in West Lafayette, Tipicanoo County, Indiana, USA while heading for a breeding pond. The salamander was returned to the laboratory and maintained in a 75.7-liter aquarium with moist paper towels and allowed to defecate. Fecal material was collected on 12 February and left in a thin layer of tap water at room temperature for three days for oocysts to sporulate. Oocysts were concentrated using coverslip flotation with Shether's sugar solution (sp. gr. 1.30), centrifuged at 1300 RPM for 5 minutes, and measured using an ocular micrometer. All measurements are reported in micrometers and given as a mean followed by a range in parentheses. Two species of coccidians, *Eimeria urodela* and *E. ambysomae*, were found to infect *A. tigrinum*. *Eimeria urodela* oocysts (N = 9) were spheroid in shape and had a smooth colorless wall 1 mm thick and possessed no micropyle. Average size of oocysts was 21.56 x 21.25 mm (20.03–23.06 x 19.84–23.31) with 4 lanceolate shaped sporocysts 14.88 x 5.8 mm (13.12–15.90 x 4.7–6.8) and a granular sporocyst residuum. *Eimeria ambysomae* oocysts (N = 5) were ellipsoid in shape 27.94 x 16.51 mm (27.02–29.76 x 14.88–17.36) and had a smooth colorless wall 1 mm thick and possessed no micropyle. Sporocysts were lanceolate in shape 15.37 x 5.1 mm (14.91–16.33 x 5.1–7). Both species were previously reported from *A. tigrinum* from northeast Colorado and northern New Mexico (Duszynski et al. 1972. J. Protozool. 19:252–256). Additionally, *E. ambysomae* has been reported from *A. tigrinum* from Iowa by Saxe (1955. Proc. Iowa Acad. Sci. 62:663–673) and *A. texanum* from Arkansas and Texas by Upton et al. (1993. Can. J. Zool. 71: 2410–2418). No reports of these species exist from Indiana (see Upton et al., *op. cit.*). Therefore, this observation extends the range of both species. Coccidia in caudate amphibians are relatively rare. However, as stated by Upton et al. (*op. cit.*), many species remain to be surveyed and resurveyed from different locations. Fourteen blue-spotted salamanders, *A. laterale*, collected in Waukesha County, Wisconsin, a two-lined salamander, *Eurycea bislineata*, and four red-backed salamanders, *Plethodon cinereus*, collected in Tipicanoo County, Indiana during April–May 1999 were negative for coccidians.

I thank Melissa Ewert, Scott Storandt, and Brian Mack for help in collecting salamanders.

BOLITOGLOSSA MELIANA (NCN). **ANTIPREDATOR POSTURE.** Although neotropical plethodontids comprise almost half of all known salamander species, most aspects of their biology are poorly understood. A few authors (e.g., Dodd and Brodie 1976. Herpetologica 32:269–290; Brodie 1982. Natl. Geogr. Soc. Res. Rep. 14:77–87) have studied antipredator adaptations among these salamanders and found, that aside from tail autotomy and a few species with strong skin toxins, most species exhibit other antipredator behaviors. In many salamanders, specific postures are an important aspect of the behavioral responses to predators. The antipredator postures of salamanders are composed of different elements of which six, so far, have been observed in neotropical plethodontids (Brodie, *op. cit.*). *Bolitoglossa meliana* is a large, uniform black, species of the *B. franklini* group. The species is known from cloud and oak-pine forest at intermediate to high elevations in the provinces of El Quiché, Baja Verapaz, Zacapa, and El Progreso, Guatemala (Wake and Lynch 1982. Herpetologica 38:257–272).

On 4 July 1999, a young *B. meliana* was found inside a rotting log on a slope in humid oak-pine forest near Santa Rosa Pass (15°03'89"N, 91°06'76"W), 8–9 km NE Santa Cruz del Quiché, El Quiché, Guatemala, at an elevation of ca. 2600 m. Dislodging the specimen from its cover elicited the following antipredator posture (Fig. 1): the salamander coiled its body, placing its head near the base of the tail. The limbs were clasped to the sides of the body and the tail was placed on top of the head. The tip of the tail was elevated and slowly undulated. During tail undulation only

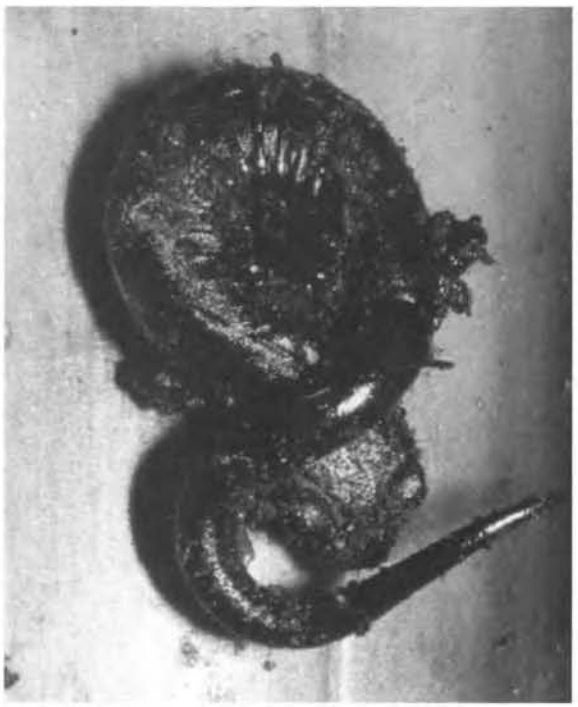

FIG. 1. A young *Bolitoglossa meliana* in antipredator posture, near Santa Rosa Pass, El Quiché, Guatemala.

the tip was moving, whereas the rest of the body was completely immobile.

The following elements (after Dodd and Brodie, *op. cit.* and Brodie, *op. cit.*) in the antipredator posture of *B. meliana* could be identified: 1. immobility; 2. body coiling; 3. tail elevation; 4. tail undulation; and 5. limbs clasped. These elements have also been observed in *B. franklini* and *B. lincolni*, both members of the *Bolitoglossa franklini* group (Brodie, *op cit.*). Both species also exhibited an arching of the body, which could not be identified in the antipredator posture of *B. meliana*.

I thank Rafael Fonoll, Sorin Damian, and Erik Keyster, who accompanied me on the field trip to Guatemala.

Submitted by **THOMAS BILLE**, Bellmansgade 40 st. tv., 2100 København Ø. Denmark.

EURYCEA QUADRIDIGITATA (Dwarf Salamander). **LARVAL PREDATION**. On 5 April 1999 in Natchitoches Parish, Louisiana, USA, in the Kisatchie National Forest in a small pool (3.6 m x 2.5 m; 22 cm deep), a larval *Eurycea quadradigitata* was found in the claws of a crayfish (*Procambus* sp.). The crayfish had eaten the head and gills of the salamander. The remains of the body were 6–7 mm long.

Petranka (1997. Salamanders of the United States and Canada. Smithsonian Institution Press. 592 pp.) suggested that crayfish may be a significant predator of larval *E. quadridigitata*. However, this is the first report of *E. quadridigitata* being preyed upon by a crayfish.

Pseudacris crucifer tadpoles were present and occupied the upper depths of the pool. The larvae of the *Eurycea* were found only beneath layers of dead leaves at the bottom of the pool. It is possible that this niche utilization may expose larval *E. quadridigitata* to other benthic predators of ephemeral pools.

Submitted by **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, 650 South R.L. Thorton Fwy. (I-35), Dallas, Texas 75203, USA; e-mail HERPKING@ix.netcom.com.

NECTURUS MACULOSUS (Mudpuppy). **EGG PREDATION**. Several researchers have documented conspecific egg predation by *Necturus maculosus* (Bishop 1941. New York State Mus. Bull. No. 324:18–37; Eycleshymer 1906. Am. Nat. 40:123–136; Hamilton 1932. Copeia 1932:83–86; Harris 1959. Field and Laboratory 27:105–111) and have suggested that the eggs may be eaten by both breeding and non-breeding individuals. However, the reproductive states of the *N. maculosus* found eating eggs were not verified in the literature.

On 1 June 1999, while searching for *N. maculosus* nests in Little Yellow Creek (40°34'08"N, 79°01'06"W), Indiana County, Pennsylvania, USA, we discovered a heavily predated nest with an adult *N. maculosus* (184 mm SVL, 265 mm TL, 95 g mass) present. The adult was captured and taken to the laboratory at Indiana University of Pennsylvania where it was euthanized and dissected. Prior to anesthetization, the animal regurgitated 30 eggs in an 18.9-liter bucket used for transport. Dissection of the stomach revealed 22 additional eggs.

The animal was a sexually mature female as indicated by her size and the presence of ovaries and oviducts. The average diameter of twenty randomly chosen follicles was 0.97 mm (SD 0.18, range 0.48–1.22 mm). The presence of small follicles in the ovaries and thin oviducts indicated that the female was not reproductively active and could not have laid eggs this breeding season.

This is the first documentation of conspecific egg predation by a non-nesting female *N. maculosus*. There was no sign of the *N. maculosus* that laid the eggs and no indication whether she had abandoned the nest or was displaced by the nest intruder.

I thank Yellow Creek State Park for permission to conduct research within the park and Arthur Hulse for his help and comments on this manuscript. Research was conducted under scientific collector's permit 057 from the Pennsylvania Fish and Boat Commission. Partial funding was provided through a grant from the Graduate School and Research, Indiana University of Pennsylvania, Indiana, Pennsylvania.

Submitted by **OWEN M. LOCKHART**, Department of Biology, Indiana University of Pennsylvania, Indiana, Pennsylvania 15705, USA.

PLETHODON CINEREUS (Redback Salamander). **PREDATION**. Few reports of terrestrial arthropods preying upon amphibians have been published (McCormick and Polis 1982. Biol. Rev. 57:29–58). While two reports describe beetles preying upon anurans (Littlejohn and Wainer 1978. Victorian Nat. 95:251–252; Robertson 1989. Herpetol. Rev. 20:7–8), the following observation appears to be the first record of a beetle preying upon a salamander.

On 13 October 1999 at 1600 h, we observed a large rove beetle (*Platydracus viduatus* Fabricius 1801, formerly *Staphylinus maculosus*; Family Staphylinidae) consuming a live redback salamander (*Plethodon cinereus*). The beetle and salamander were found underneath a 1 ft^2 untreated coverboard at the USGS Patuxent Wildlife Research Center in Laurel, Maryland (UTM zone 18, 4323755 N, 345070 E, 30 m elevation, air 20.5°C). As the coverboard was lifted, the rove beetle (24 mm total length) was next to the redback salamander, but immediately retreated several cm and assumed a defensive posture in which the abdomen was raised and curved slightly over the body. The salamander (red phase, 40 mm SVL, 76 mm TL) was unusually thin. Its maximum width was 3.5 mm, 1 mm less than the average width of 15 other similar-sized redback salamanders (4.5 mm ± 0.66). The salamander had a 3 x 1 mm wound ca. halfway between the front and hind limbs and was partially eviscerated, but was still alive. The salamander's front limbs were on the ground, but the lower half of its body was twisted such that the lower legs, the puncture wound, and the eviscerated intestinal tract were facing upward. The last 18 mm of the salamander's tail was detached either by the beetle or as an autotomic response to the beetle attack.

Rove beetles such as *Platydracus viduatus* are generalist predators, eating a variety of invertebrates ranging from small nematodes, aphids, mites, dipterans, and collembolans, to larger organisms such as earthworms, larvae and adults of beetles and other insects (Krooss and Schaefer 1998. Ann. Appl. Biol. 133:1–16). *Platydracus viduatus* probably locates its prey by tactile contact during locomotor activity (Wheater 1989. J. Zool., Lond. 218:171–185). The rove beetle herein described may have been able to opportunistically attack and feed on the redback salamander

because the latter was weak and therefore unable to escape from or fend off the beetle.

We thank Lee Herman, Curator of Coleoptera at the American Museum of Natural History, for identifying the beetle, Sam Droege for establishing the coverboard transect, and Robert Fernandes for measuring the width of redback salamanders.

Submitted by **ROBIN E. JUNG, WENDY L. WARD, CARLOS O. KING**, and **LINDA A. WEIR**, USGS Patuxent Wildlife Research Center, 12100 Beech Forest Road, Laurel, Maryland 20708, USA.

ANURA

BUFO BOREAS (Boreal Toad). **PREDATION**. Several birds have been reported as predators of *Bufo boreas* and their tadpoles. Here we report predation on adult *B. boreas* by the red-tailed hawk (*Bueto jamaicensis*). Since 1995, we have been attaching radio transmitters to adult boreal toads as part of our monitoring procedures in a population near Berthoud Pass in Clear Creek County, Colorado, USA. Toads with transmitters are located weekly during the activity season. On two occasions in 1999 (14 July and 3 August), we tracked radio signals of two marked male *B. boreas* to a red-tailed hawk nest 10 m above the ground in an Engelmann spruce (*Picea engelmannii*). The hawk nest was located at 3200 m elevation ca. 400 m from the nearest *B. boreas* breeding site. Distances to the nest from the last recorded locations of the toads were 300 and 310 m. This is the first record of predation on *B. boreas* by a raptor in five years of observations at this site.

Funding for this work was provided by Great Outdoors Colorado through the Colorado Division of Wildlife. We thank Anne Beierle, Environmental Coordinator, and the Climax Molybdenum Company for facilitating research activities. Lauren J. Livo commented on a draft of this note.

Submitted by **MARK S. JONES** and **BUD STILES**, Colorado Division of Wildlife, 317 West Prospect Road, Ft. Collins, Colorado 80526, USA.

BUFO PUNCTATUS (Red-spotted Toad). **LARVAL COLORATION**. On 24 June 1999, I observed a single albino *Bufo punctatus* tadpole in No Thoroughfare Canyon, Colorado National Monument, Colorado, USA. The albino tadpole was within the same size and developmental range as ca. 50 normally colored tadpoles in the same pool (mean ± SD: SVL = 10 ± 1 mm, TL = 24 ± 3 mm, developmental stage = 31 ± 1; N = 10; Gosner 1960. Herpetologica 16:183–190). Although *B. punctatus* tadpoles occupied several pools within the canyon, this was the only albino observed. In 1979, Luepschen (1981. Herpetol. Rev. 12:79) observed six albino *B. punctatus* tadpoles in the same canyon. To my knowledge, albino adult *B. punctatus* have not been reported from Colorado National Monument or elsewhere (Dyrkacz 1981. Herpetol Circ. No 11). However, observations separated by 20 years of albino tadpoles within the same canyon suggest that this population retains at least low frequencies of the appropriate genotypes to produce albinos.

Funding for this work was provided by Great Outdoors Colorado and the Colorado Division of Wildlife.

Submitted by **LAUREN J. LIVO**, Colorado Division of Wildlife, 317 West Prospect Road, Ft. Collins, Colorado 80526, USA and EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

BUFO PUNCTATUS* and *BUFO WOODHOUSII (Red-spotted Toad and Woodhouse's Toad). **HYBRIDIZATION**. Many anurans are known to hybridize in nature and toads, genus *Bufo*, have long been subjects of hybridization research (Blair 1972. Evolution in the Genus *Bufo*. University of Texas Press, Austin. 459 pp.). Hybridization between *B. punctatus* and *B. woodhousii* explains morphologically intermediate toads collected from Lava Canyon (River Mile 65.5) of the Grand Canyon (Arizona State University 28398) and Glen Canyon (Museum of Northern Arizona Z6.527–528) in Arizona (Malmos et al. 1995. Great Basin Naturalist 55:368–371). Furthermore, other distantly related toad species (e.g., *B. alvarius* x *B. woodhousii* and *B. cognatus* x *B. woodhousii*) are known to hybridize in Arizona (Gergus et al. 1999. Copeia 1999:281–286). Although discovery of hybrids in nature implies mismating between species, heterospecific amplexus is rarely observed (KBM, pers. obs.). Here we report backcross amplexus between a hybrid *B. punctatus* x *B. woodhousii* and *B. woodhousii* and heterospecific amplexus between *B. punctatus* and *B. woodhousii*.

On 12 May 1998 at 1037 h, a male *B. punctatus* x *B. woodhousii* (verified as hybrid by B. K. Sullivan from photo, Fig. 1) was observed in amplexus with a female *B. woodhousii* at Nankoweap Twin Springs, ca. 4 km above the Colorado River (RM 52). The pair was found in shallow water over cobble. The male was diagnosed as a hybrid by possession of morphological characteristics intermediate to the two species: dorsum with some red warts, lack of a mid-dorsal stripe and dorsal blotches, parotoid gland wedge-shaped, weak cranial crests, and slightly flattened head. Two additional *B. woodhousii* were observed among cattails at the spring, but no other *B. punctatus* were found nearby.

On 11 May 1999 at 2040 h, a male *B. punctatus* was observed in amplexus with a female *B. woodhousii* in Hermit Creek, within

FIG. 1. Male *Bufo punctatus* x *B. woodhousii* in amplexus with a female *B. woodhousii* at Nankoweap Twin Springs, ca. 4.0 km from the Colorado River, Grand Canyon, Arizona.

100 m of the Colorado River (RM 95). The pair was found in shallow water flowing over exposed gravel. Water and air temperature were 19°C and 25.5°C. Approximately 12 *B. punctatus* were calling at this site, and no other *B. woodhousii* were seen or heard at this aggregation. Lack of enlarged, darkened thumb pads and failure to give release calls when the pair was in hand, indicated the *B. woodhousii* was female in both cases. During handling, the males never released females and amplexus continued after release. It is not known whether eggs were deposited in either case. Females of the less abundant species mating with males of the more common species is a typical pattern in hybridization (Wirtz 1999. Animal Behavior 58:1–12).

Submitted by **BRUCE CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87025, USA, **KEITH B. MALMOS** and **ANDREW T. HOLYCROSS**, Arizona State University, Department of Biology, Tempe, Arizona 85287-1501, USA, and **ROY C. ELEUTHERODACTYLUS COQUI (Coqui). **PREDATION**. The scorpion, *Tityus obtusus* is a known predation of preadult and adult *Eleutherodactylus coqui* in the field and in captivity (Steward and Woolbright 1996. *In* Reagan and Waide [eds.], The Food Web of a Tropical Rain Forest. Univ. Chicago Press.) although no information on prey size has been published. Here we report a predation event on a juvenile *E. coqui* in the field. At 2000 h on 18 September 1998 at the University of Puerto Rico El Yunque Field Station (18°17'58"N, 65°46'43"W) we found a scorpion (*T. obtusus*, Museo de Biología, Universidad de Puerto Rico-Recinto de Río Piedras UPRRP 154) under a fern frond (137 cm above the ground) grasping a juvenile *E. coqui* (17 mm SVL, UPRRP 5751). The scorpion used its left pedipalp to support the frog by the pelvic region, while keeping a firm grasp with its chelicerae on the prey's left hind leg (Fig. 1). The frogs's left tibio-fibula was completely exposed at the time the predation event was observed.

FIG. 1. *Eleutherodactylus coqui* captured by a scorpion, *Tityus obtusus*.

HYLA SQUIRELLA (Squirrel Tree Frog). **REPRODUCTION**. The squirrel treefrog ranges throughout the southeastern coastal plain of the United States, including all of Florida. (Conant and Collins 1991. Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). It is considered a spring/summer breeder and is known to reproduce from March through October in the southern portion of its range (Carr 1940. Univ. Florida Publ. Biol. Sci. 3:1–118; Wright and Wright 1995. Handbook of Frogs and Toads of the United States and Canada. 3rd ed. Comstock Publ. Co., Ithaca, New York, 640 pp.; Conant and Collins, *op. cit.*). We report an observation of breeding that occurred earlier than the reported reproductive period.

On 23 January 1999 at ca. 2000 h, we encountered a small chorus of *Hyla squirella* at a recently-mowed roadside ditch in Volusia County, Florida between Deland and Daytona Beach. Earlier that evening the ditch had been filled by heavy rainfall associated with a weak cold front. *Hyla squirella* males were observed calling from the shore of the ditch, at the water's edge, and while floating. We collected an amplectant pair (female 37 mm SVL, male 31 mm SVL) that was floating on the surface. Eggs were visible through the inguinal body wall of the female. *Pseudacris nigrita* and *P. ocularis* were heard calling in the distance. To our knowledge, this is the first published account of *H. squirella* breeding during January. The frogs were deposited in the herpetology collection of the Florida Museum of Natural History, University of Florida (UF 119001–119002).

Submitted by **STEVE A. JOHNSON** and **RYAN C. MEANS**, Department of Wildlife Ecology and Conservation, and Florida Museum of Natural History, University of Florida, Gainesville Florida 32611, USA.

LEPTOPELIS VIRIDIS (West African Tree Frog). **COCOON FORMATION**. *Leptopelis viridis* (Hyperoliidae) is a fossorial amphibian that occurs throughout West Africa both in the dry and humid savanna (Schiøtz 1967. Spolia Zool. Mus. Haun. 25:1–346.). Little is known about the ability of this species to conserve water during the dry season although this important life-history aspect has been studied in other West African savanna denizens (Linsenmair 1997. *In* Newbery et al. [eds.], Dynamics of Tropical Communities, pp. 221–241. Blackwell Science, Oxford). Here I describe cocoon formation in a specimen of *L. viridis* collected in the Guinea savanna region of the Comoé National Park, Ivory Coast, that was subsequently observed in other individuals. In 1997, an adult female was brought into the laboratory where she was kept in a terrarium at a day-night temperature and humidity cycle of 20–26°C and 60–70% RH. In February 1998, the female was left unattended, i.e., without spraying water, and she subsequently burrowed into the substrate. Approximately two months later the loose soil that filled the bottom of the terrarium was carefully sifted. The female was found in a characteristic water-conserving posture like that found in other cocoon forming species (Withers 1995. Aust. J. Zool. 43:429–441) 10 cm underground encased in a tight, semi-transparent cocoon that covered the eyes but left the external nares open (Fig 1.). The female was carefully handled and was immediately responsive to touch. She was left largely undisturbed

FIG. 1. Adult female *Leptopelis viridis* encased in a semi-transparent cocoon.

for 40 min, during which time limb movements and breathing increased. She was then sprayed with water. Shortly afterwards, the female repeatedly stretched her mouth, progressively increasing her gape width. At one point, this caused the cocoon to rip open dorsally, starting at the mouth. The female emptied her bladder and, using her limbs, completely stripped the cocoon from her body. Within the family Hyperoliidae, cocoon formation, although mentioned for *L. viridis* by A. Schiøtz (Loveridge 1976. Zoologica Africana 11:319–333) has been described only in *L. bocagei* (Loveridge and Craye 1979. S. Afr. J. Sci. 75:18–20.). The observation that *L. viridis* forms cocoons adds to the repertoire of water conservation strategies in West African anurans.

RANA AREOLATA CIRCULOSA (Northern Crayfish Frog). **VOCALIZATION**. On 2 April 1999 at ca. 2000 h at a small, virgin tall-grass prairie in Dade County, Missouri, USA, we heard several unusual ranid frog calls. The calls were similar to *Rana areolata* but sounded muffled. Upon further investigation, we discovered a full chorus (>10 males) of *R. areolata* vocalizing underwater. PWF had searched this area on 29 March 1999 and heard a chorus (<8 males) of *R. areolata* vocalizing on the surface at the same location. That chorus could be heard from over 0.5 km away, however the 2 April chorus could be faintly heard at a maximum distance of 200 m. Underwater vocalization of *R. areolata* has been reported (Barbour 1971. Amphibians and Reptiles of Kentucky. Univ. of Kentucky Press. Lexington. 334 pp.). This behavior could adversely affect calling surveys.

Submitted by **PAUL W. FRESE** and **AARON M. SULLIVAN**, Department of Biology, Southwest Missouri State University, 901 South National, Springfield, Missouri 65804, USA; e-mail pwf035s@mail.smsu.edu.

RANA CAPITO AESOPUS (Florida Gopher Frog). **ECTOPARASITES**. *Rana capito aesopus* utilizes the burrow of the gopher tortoise (*Gopherus polyphemus*). This habit puts the frog in contact with numerous invertebrate species. On 21 May 1999 at Rock Springs Run State Reserve, Florida, USA, I caught a large female gopher frog (119.5 g; 9.7 cm SVL) and removed six nymphs of *Ornithodoros turicata* (US National Tick Collection RML122857) from the ventral surface of the frog. Although all the parasites were firmly attached to the frog, and were fairly difficult to remove, the individual appeared healthy and unharmed. On 13 September 1999, not far from the previous capture, I caught an adult male gopher frog (47.0 g; 7.5 cm SVL) with one *O. turicata* attached to its right front limb. Although this tick was larger, it still appeared to have no effect on the frog. Both the frogs were released at point of capture.

Although *Ornithodoros turicata* has been reported on gopher frogs previously (Milstrey 1987. Bionomics and Ecology of *Ornithodoros* (*P.*) *turicata americanus* (MARX) (Ixodoidea: Argasidae) and other Commensal Invertebrates Present in the Burrows of the Gopher Tortoise, *Gopherus polyphemus* Daudin. Univ. of Florida Dissertation, 131 pp.), this information has not been published in a herpetological journal.

Great thanks go to J. E. Keirans of the U.S. National Tick Collection at Georgia Southern University for identification of the tick specimens. Also, thanks to Jack Stout of the University of Central Florida, Shane Belson, and Stuart Fullerton.

Submitted by **W. BOYD BLIHOVDE**, Department of Biology, University of Central Florida, 4000 Central Florida Blvd., Orlando, Florida 32816, USA.

RANA CAPITO SEVOSA (Dusky Gopher Frog). **METAMORPH CAPTURES**. The dusky gopher frog is found primarily along the Coastal Plain region of the Florida panhandle westward across Alabama and into Mississippi. It is thought to spend most of its adult life underground, frequently using the burrows of the gopher tortoise, *Gopherus polyphemus*, and is considered to be a species at risk in Alabama (Means 1986. *In* Mount [ed.], Vertebrate Animals of Alabama in Need of Special Attention. Alabama Agri. Expt. Station, Auburn University. 124 pp.). Only six ponds in Alabama have been documented as traditional breeding ponds, one of which (Shelby County) has likely been ruined by a housing development under construction. Two of these ponds, Nellie Pond and Salt Pond, are found in the Conecuh National Forest, Covington County (M. Bailey, pers. comm.). Practically nothing is known about the life history of the adult, and especially the metamorphs. We find no published records of *R. c. sevosa* metamorph captures from the wild in Alabama. Mark Bailey and Chris Oberholster captured one metamorph from the edge of Nellie Pond in June 1993 (M. Bailey, pers. comm.).

On 21 May 1999 at Nellie Pond, we saw three *R. c. sevosa* metamorphs. One (SVL 37.5 mm) was captured at the mouth of a gopher tortoise burrow at 1950 h, just a few minutes before dark. It did not attempt to move until capture was imminent. Temperature and relative humidity at 1900 h were 24.4°C and 68% at the USDA Forest Service Work Center at Open Pond, a few miles away. Two additional metamorphs were seen at 2020 h hopping on the sand road just outside the Nellie Pond access gate, located about 30 m from the edge of the pond. While one escaped into a thicket, the other was captured (SVL 36.8 mm). By 2000 h the temperature

had decreased to 22.8°C and relative humidity had risen to 75%. For about another hour we slowly searched for metamorphs on the pond perimeter.

On 11 June, MRB, KNB, and AFB searched along the Nellie Pond perimeter road from 2030–2100 and 2210–2345 h, and along the entire margin of Nellie Pond from 2105–2210 h during a gentle rain with thunder and lighting in the distance. At 2235 h we captured a metamorph (SVL 32.3) in the middle of the sandy road. This frog never moved even though it was almost stepped on, indicating that searchers should anticipate little or no mobility of these frogs as they are approached. Temperature at 2200 h was 21.1°C with relative humidity at 99%. At 2300 h temperature was still 21.1°C with relative humidity at 100%.

MRB searched along the perimeter road from 0230–0315 h, then three of us searched along this road and in the gopher tortoise burrow fields for several hours beginning at 0500 h. At 0550 hr we captured a metamorph with an obvious tail remnant (SVL 34.6, tail 3.7 mm) about 3 m from the entrance to a different gopher tortoise burrow, out in the open on sand. This metamorph also moved only when being captured. At 0600 h temperature was 21.1°C and relative humidity was 100%. SVL of these metamorphs fall within the range reported from western Florida (Palis 1998. J. Herpetol. 32:217–223), but are less than those observed in South Carolina (Semlitsch et al. 1995. J. Herpetol. 29:612–614.).

We thank Rick Lint, USDA Forest Service, for temperature and relative humidity data.

RANA MUSCOSA (Mountain Yellow-legged Frog). **PREDATION**. *Rana muscosa* is a moderate-sized, high elevation frog restricted to California and the Lake Tahoe region of western Nevada (Zweifel 1968. Cat. Amer. Amphib. Rept. 65:1–2; Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. California Dept. Fish and Game. 255 pp.). Native predators of *R. muscosa* include *Thamnophis elegans*, *Euphagus cyanocephalus* (Brewer's blackbird), *Nucifraga columbiana* (Clark's nutcracker), and *Canis latrans* (coyote) (Bradford 1991. J. Herpetol. 25:174–177; Camp 1917. Univ. California Publ. Zool. 17:115–125; Jennings et al. 1992. J. Herpetol. 26:503–505; Moore 1929. J. Mamm. 10:255). Here we report two additional predators of *R. muscosa*.

On 9 August 1999 during herpetological surveys of the Tahoe National Forest, we caught a male *T. sirtalis fitchi* (SVL 416 mm, tail 142 mm, 31.56 g, California Academy of Science 209984) at an unnamed pond 8.8 km. NE of Cisco Grove via Rattlesnake Rd., Nevada Co., California (39° 20'10.5"N, 120°28'48.0"W) from which we palped a partially digested juvenile *R. muscosa* (SVL ca. 33 mm, 1.97 g, stomach contents of CAS 209984).

We also encountered a juvenile *R. muscosa*. (SVL 30 mm, 1.64 g, CAS 210033) among the *Juncus* sp. and *Carex* sp. 1 m from the pond shore at the surface of water 30 cm deep. The *R. muscosa* was weakly struggling with a larval *Dytiscus* sp. (predaceous diving beetle) (total length ca. 50 mm, 1.16 g, held with CAS 210033) that was attached to the frog's left thigh by penetrating mandibles. We collected both *R. muscosa* and *Dytiscus* sp. at which time the dytiscid larva released the frog. Upon observing the *R. muscosa*, the left leg remained extended, apparently unusable, and the left thigh was discolored by massive hemorrhaging around the bite area. The *R. muscosa* was placed in a moist plastic bag, and kept cool until later that day. Inspecting the *R. muscosa* two hours later, we found it had died, probably from the effects of the proteases injected by the dytiscid larva's mandibles (Young 1967. Pan-Pac. Entomol. 43:113–117). Though an increasing number of incidents of predation by invertebrates, especially insects and spiders on both adult and tadpole frogs have been reported (e.g., predation of *Ascaphus truei* by a helgrammite, Jones and Raphael. 1998. Herpetol. Rev. 29:39; predation of *R. cascadae* by a giant water bug, Nauman and Dettlaffe. 1999. Herpetol. Rev. 29:93) this is the first case for *R. muscosa*, a state listed species of special concern in California, and suggests that newly metamorphosed *R. muscosa* may be vulnerable to other predatory aquatic macroinvertebrates (Formanowicz and Brodie 1982. Copeia 1982:91–97).

We thank Jens Vindum and Marylin Tierney for their supervision during this field work, which was funded by a Challenge Cost-Sharing Agreement between the CAS and the U.S. Department of Agriculture, Forest Service Region 5 (CCS-5-99-20-069).

Submitted by **CHRIS R. FELDMAN**, Department of Biology, San Francisco State University, San Francisco, California 94132, USA and **JEFFREY A. WILKINSON**, Department of Herpetology, California Academy of Sciences, San Francisco, California 94118, USA.

TESTUDINES

CARETTA CARETTA (Loggerhead Sea Turtle). **EPIZOANS**. Although epizoic organisms occur on all seven species of marine turtles, *Caretta caretta* hosts the largest and most diverse communities (Frick et al. 1998. Herpetol. Rev. 29:211–214). Much of the data concerning *Caretta* and its epibiota in the southeastern U.S. come from nesting females (Caine. 1986. J. Exp. Mar. Biol. Ecol. 95:15–26 and Frick et al. 1998. *op. cit.*). To our knowledge, only one study reports the occurrence of epizoa on subadult *Caretta* (Frazier et al. 1985. Mar. Ecol. 6:127–140). However, the two turtles sampled by Frazier et al. (1985. *op. cit.*) were dead strandings and it is therefore possible that epizoan attachment occurred post-mortem. Herein, we report four newly documented species of epizoans associated with living subadult *Caretta* in Georgia, USA.

From 12 to 16 February 1999, 33 subadult *Caretta* were collected from the St. Mary's River Entrance Channel (30°42.7'N, 81°20.1'W). Prior to channel dredging operations, a specially modified shrimp trawler was used to collect any sea turtles located within a specified hopper dredge digging area. While on board the trawler, turtles were measured, tagged, and sampled for epibiota. Turtles were then relocated to estuarine waters, away from the digging area, immediately west of Cumberland Island National Seashore (Cabin Bluff, 30°53.0'N, 81°30.8'W).

All captured turtles were *Caretta* of subadult age class (51.8–77.0 cm CCL) as defined by Dodd (1988. U.S. Fish Wildl. Serv.

Biol. Rep. 88:1–110). Every turtle sampled contained the following epizoan species: turtle barnacles (*Chelonibia testudinaria*), hermit crab anemones (*Aiptasia pallida*), pink-striped acorn barnacles (*Balanus amphitrite*), and wildflower hydroids (*Tubularia crocea*). Moreover, all turtles sampled had a similar colonization pattern. Barnacles abounded over the entire carapace, especially along the sutures where scutes met. Hydroids preferred any area on the carapace free of barnacle colonization. Anemones (1 or 2 attached to each turtle sampled) were located on the fourth and fifth costal scutes on either side of the turtle.

These observations are of interest because the relationship between sea turtles and their epibiota is a poorly studied aspect of sea turtle natural history. Noting the occurrence and prevalence of epibiont species may help us to better understand the natural history of these turtles away from their nesting beaches.

We thank Christopher Carroll, Lindsey Parker, Tim O'Toole, Eric Hawk, Randy Isbister, Anne M. Frick, John Robinette, Charles Warnock, Mark Dodd, Adam MacKinnon, Barb Zoodsma, and Robert A. Moulis. This research was conducted under NMFS permits outlined according to NMFS protocols and regulations regarding sea turtle relocation.

Submitted by **MICHAEL G. FRICK**, Caretta Research Project, P.O. Box 9841, Savannah, Georgia 31412-9841, USA (e-mail: Caretta05@aol.com), and **CHRISTOPHER K. SLAY**, Coastwise Consulting, 173 Virginia Avenue, Athens, Georgia 30601, USA.

CHELONIA MYDAS AGASSIZII (East-Pacific Green Turtle). **DIET**. Immature and adult *Chelonia mydas agassizii* are known to have a more carnivorous diet than *Chelonia* of other regions (Bjorndal 1997. *In* Lutz and Musick [eds.], The Biology of the Sea Turtles, pp. 165–198. CRC Press, Boca Raton, Florida). Felger and Moser (1973. Science 181:355–356) and Hays-Brown and Brown (1995. *In* Bjorndal [ed.], Biology and Conservation of the Sea Turtles, pp. 235–240. Smithsonian Institution Press, Washington D.C.) reported these turtles feeding on a wide variety of invertebrates, and Casas-Andreu and Gomez-Aguirre (1980. Bolm. Inst. Oceanogr. Sao Paulo 29:87) and Fritts (1981. Mar. Turtle Newsl. 17:4–5) noted feeding on fish and fish eggs. Here we report on the consumption by *C. m. agassizii* of the solitary cnidarian, *Ptilosarcus undulatus* (fleshy sea pen), Order Pennatulacea.

Between June 1996 and September 1998, 109 *C. m. agassizii* were captured at the Bahia de los Angeles foraging grounds of the Gulf of California, Mexico (28°58'N, 113°33'W). *Ptilosarcus undulatus* was recovered from 5.8% (6 of 103) of gastric lavage samples and 29.3% (17 of 58) of fecal samples. Body mass and straight-carapace length (SCL) of turtles that consumed *P. undulatus* ranged from 42–104 kg and 64.7–89.2 cm, respectively. This SCL range includes both subadults and adults (Green 1993. J. Herpetol. 27:338–341).

Plotkin et al. (1993. Mar. Bio. 115:1–15) recorded sea pen (*Virgularia presbytes*) consumption by *Caretta caretta*, and Shaver (1991. J. Herpetol. 25:327–334) found the same species in the diet of *Lepidochelys kempii*. However, to our knowledge this is the first report of *Chelonia* foraging on Pennatulaceans, and appears to be the first account of sea pen consumption by sea turtles in the Pacific Ocean basin.

We thank Earthwatch Institute and the many team members who assisted in this study. This research was authorized by the Secrcretaría del Medio Ambiente, Recursos Naturales, y Pesca, Mexico (Permisos Pesca de Fomento Números 150496-213-03, 280597-213-03, 190698-213-03).

CHRYSEMYS PICTA PICTA (Eastern Painted Turtle). **MAXIMUM SIZE**. The maximum size for *Chrysemys picta picta* is given as 18.1 cm carapace length (CL) by Conant and Collins (1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin, Boston, Massachusetts. 450 pp.). However, Rhodin and Mittlehauser (1994. Chel. Conserv. Biol. 1:148–150) reported capturing three specimens in Maine that exceeded this size, one of which was 18.7 mm CL. There are three female specimens from New Brunswick, Canada, in the New Brunswick Museum (NBM) collection that exceed 18.1 cm CL, including one that is larger than any of the Maine specimens (Table 1). Carapace measurements were taken in a straight line and did not include indentations in the nuchal and between the two rearmost marginals. The specimens were identified as *C. p. picta* on the basis of collection locality, lack of a plastral pattern (for NBM-01087 and 0637), low disalignment of carapacial scutes (using the method of Hartman 1958. Copeia 1958:261–265; values for

TABLE 1. Carapacial and collection data for three large female *Chrysemys picta picta* from New Brunswick, Canada. Carapace length given as mean ± S.E.

Catalog Number	Carapace length (cm)	% Disalignment of carapacial scutes	Light margin width (cm)	Collection Data
NBM-01087	18.58[a] ± 0.01	29.33	0.53	June 1985 Grand Lake, Queens County, D. F. McAlpine
NBM-0832	18.98[b] ± 0.01	33.99	0.54	25 June 1973 Gagetown, Queens County, J. Sinclair
NBM-0636	18.44[b] ± 0.00	48.88	0.60	Sept 1965 Hampton Kings County

[a] mean of 5 measurements taken with vernier calipers accurate to 0.01 cm.
[b] mean of 10 measurements taken using an electronic digital readout (Anilam Electronics Corp., Miami, Florida) on an adjustable drill press bench accurate to 0.001 cm.

C. p. marginata are typically >80%, Ultsch and LeBerte, unpubl. data), and the wide light anterior margins of the carapacial scutes (mean of the two 2nd laterals, Hartman *op. cit.*). The three specimens from Maine were the largest of a sample of 122 mature females, while the three from New Brunswick were from a sample of only 14. Our data supports Rhodin and Mittelhauser's (*op. cit.*) contention that size of eastern painted turtles increases with increasing latitude.

LACERTILIA

CROTAPHYTUS COLLARIS (Eastern Collared Lizard) and ***DIADOPHIS PUNCTATUS*** (Ringneck Snake). **PREDATOR-PREY**. On 13 April 1998 while marking collared lizards for behavioral studies at Arcadia Lake Dam, Edmond Oklahoma, USA, I observed a dead *Diadophis punctatus* (324 mm TL, 6.8 g) in the gullet of a female *Crotaphytus collaris* (99 mm SVL, 43.5 g w/ snake removed). The snake was 15.6% of the lizard's body mass, and over twice the length of the lizard. Eighty percent of the snake's length had been swallowed past the pharynx tail first, whereas the anterior 20% of the snake was folded back posteriorly in the lizard's esophagus. This position suggests that the ringneck was grabbed by the tail, which may be noteworthy because *Diadophis* uses its tail in defensive displays (Greene 1997. Snakes: The Evolution of Mystery in Nature. Univ. California Press, Berkeley, California. 351 pp). As far as I know, this is the only reported instance of collared lizard predation on *D. punctatus*. Collared lizards have been reported to take *Sonora semiannulata* (Best and Pfaffenberger 1987. Southwest. Nat. 32:414–426) and *Opheodrys aestivus* (Husak and Ackland 2000. Herpetol. Rev. 31:in press).

SERPENTES

CROTALUS MITCHELLII (Speckled Rattlesnake) and ***CROTALUS WILLARDI*** (Ridgenose Rattlesnake). **ENDOPARASITES**. The only report of endoparasites in *Crotalus mitchellii* involves the nematode *Thubunaea cnemidophorus* (Babero and Emmerson 1974. J. Parasitol. 60:595), and to our knowledge there have been no reports of endoparasites for *Crotalus willardi*. The purpose of this note is to report the presence of larval tapeworms (cestodes) and larval spiny-headed worms (acanthocephalans) in *C. mitchellii* and *C. willardi*. The body cavities of a total of 117 *C. mitchellii* from Arizona and California and 28 *C. willardi* from Arizona and New Mexico (USA), and Sonora and Chihuahua (México), from the herpetology collections of Arizona State University, Tempe (ASU), the Natural History Museum of Los Angeles County (LACM), the University of Arizona (UAZ), and the Museum of Southwestern Biology, University of New Mexico (MSB) were examined for helminths (*C. mitchellii*: ASU, LACM, UAZ; *C. willardi*: ASU, UAZ, MSB). A mid-ventral incision was made in the body wall, and organ surfaces and mesenteries in the posterior portion of the body cavity were visually checked for helminths. Oblong whitish bodies, ca. 1 x 3 mm, were occasionally seen. These proved, upon microscopic examination, to be larval cestodes (tetrathyridia of *Mesocestoides* sp.) in *C. mitchellii* (LACM 104938) and *C. willardi* (UAZ 27943; MSB 25354, 61239) and oligacanthorhynchid acanthocephalan cystacanths in *C. mitchellii* (ASU 1606) and *C. willardi* (MSB 61241). Prevalence of infection (infected snakes/sample examined x 100) for *Mesocestoides* sp. was 1% in *C. mitchellii* and 11% in *C. willardi*, and for oligacanthorhynchid cystacanths was 1% in *C. mitchellii* and 4% in *C. willardi*. Parasite specimens were deposited in the U.S. National Parasite Collection (USNPC), Beltsville, Maryland: tetrathyridia of *Mesocestoides* sp., *C. mitchellii* USNPC 88616, *C. willardi* USNPC 88535; oligacanthorhynchid cystacanths, *C. mitchellii* USNPC 88617, *C. willardi* USNPC 88536.

Tetrathyridia of *Mesocestoides* sp. have been found in *C. atrox* and *C. viridis* (Bolette 1997a. J. Parasitol. 83:751–752; Mankau and Widmer 1977. Jap. J. Parasitol. 26:256–259). Bolette (1998. J. Helm. Soc. Washington 65:105–107) also found them in *C. viridis*. Tetrathyridia of *Mesocestoides* sp. also occur in *C. molossus* and *C. pricei* (Goldberg and Bursey 1999. Herpetol. Rev. 30:44–45). Oligacanthorhynchid cystacanths have been found in other North American crotalids: *Crotalus atrox*, *C. scutulatus*, *C. viridis* (Bolette 1997a. *op. cit.*; Bolette 1997b. Southwest. Nat. 42:232–236; Bolette 1998, *op. cit.*), *C. lepidus* and *C. tigris* (Goldberg and Bursey 1999, *op. cit.*). Rattlesnakes serve as paratenic (transport) hosts for *Mesocestoides* sp. (Bolette 1997a, *op. cit.*) and oligacanthorhynchid cystacanths (Bolette 1997b, *op. cit.*). The presence of *Mesocestoides* sp. and oligacanthorhynchid cystacanths in *C. mitchellii* and *C. willardi* are new host records and represent the first records of helminths in *C. willardi*. Including findings presented herein, *Mesocestoides* sp. are known from 4/13 (31%) and oligacanthorhynchid cystacanths from 7/13 (54%) of United States *Crotalus*.

We thank Michael E. Douglas (Arizona State University) and Charles H. Lowe (The University of Arizona) for permission to examine *C. mitchellii* and *C. willardi*, Robert L. Bezy (Natural History Museum of Los Angeles County) for permission to examine *C. mitchellii* and Charles W. Painter (New Mexico Department of Game and Fish, Santa Fe) for permission to examine *C. willardi*.

Submitted by **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu), and **CHARLES R. BURSEY**, Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA.

CROTALUS SCUTULATUS (Mojave Rattlesnake). **THERMAL STRESS**. At 1027 h on 22 July 1999, while driving on a dirt road in desert grassland habitat 44 km SE of Willcox, Arizona, USA, I observed a *Crotalus scutulatus* (ca. 1 m total length) outstretched and slowly moving with head down across the road. As my jeep approached and stopped, the snake quickly coiled and I observed a freshly killed adult ground squirrel (*Spermophilus spilosoma*)

about 50 cm in front of the snake. The snake then uncoiled and quickly crawled off the road in a direction opposite its approach to the squirrel, disappearing into roadside vegetation about 7 m from the squirrel. I responded by backing away to about 35 m from the encounter site and observed through binoculars while remaining in my jeep. At 1039 h the snake reappeared from the vegetation and crawled back and forth in the fencerow parallel to the road until abruptly turning 90° and moving directly to the dead squirrel in the road. Tongue flicking and trailing behavior was evident throughout what was obviously crotalid strike-induced chemosensory searching behavior (Chiszar et al. 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 369–382. Selva, Tyler, Texas). At 1045 h the snake began swallowing the squirrel headfirst, advancing to the shoulder region when suddenly, at 1047 h, the snake ceased swallowing and appeared frantic as it made short, jerky, undirected movements which lifted portions of its body off the substrate. The snake then lifted the squirrel and rapidly moved headfirst until it was 4.5 m off the road in the shade of the fencerow vegetation. At that time it resumed swallowing and completed ingestion by 1054 h.

Daytime feeding in exposed habitat may result in overheating and thermal stress for reptilian predators (Swingland and Frazier 1979. *In* Amlaner and MacDonald [eds.], A Handbook on Biotelemetry and Radio Tracking, pp. 611–615. Pergamon Press, New York, New York), and this unusual rattlesnake behavior suggests that such may have been the case here. Given a choice, reptiles normally cease activity long before their body temperatures approach critical levels (Huey 1982. *In* C. Gans [ed.], Biology of the Reptilia, Vol. 12, Physiology C, pp. 25–91. Academic Press, New York, New York). However, initial trailing, subsequent re-trailing after disturbance, and swallowing, all while exposed on the bare dirt substrate of the road in late morning, may have resulted in the snake's body temperature approaching a critical level. The snake's actual body temperature was unknown but the operative temperature of a nearby *Terrapene ornata* thermal model located in exposed bare dirt microhabitat (similar to the road) was 40°C at 1047 h, far above the normal field body temperature (approximately 30°C) and approaching the CTMax (39–42°C) of several *Crotalus* spp. (Lillywhite 1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 422–477. MacMillan Publ. Co., New York, New York). It was unlikely that the snake's sudden cessation of swallowing and frantic retreat to shade was in response to my presence because, after I had moved my jeep 35 m away, the snake did not appear to be aware of me.

I thank J. D. Congdon for comments on the manuscript.

DRYMARCHON CORAIS COUPERI (Eastern Indigo Snake) and ***MICRURUS FULVIUS FULVIUS*** (Eastern Coral Snake). **PREDATOR-PREY**. *Drymarchon corais couperi* is a large, nonvenomous colubrid that is threatened throughout its range. It preys on a wide variety of vertebrates, including venomous snakes (Moler 1992. Rare and Endangered Biota of Florida. Vol. 3. Amphibians and Reptiles. University Press of Florida, Gainesville, Florida. 291 pp.). Descriptions of *D. corais* preying on venomous snakes specify viperids as prey (Moler, *op. cit.*; Wright and Wright 1957. Handbook of Snakes of the United States and Canada. Vol. 1. Comstock Publishing Associates, Ithaca, New York. 564 pp.). Here, I report predation by *D. corais* of an elapid.

On 7 October 1998 at 0959 h, I discovered a *D. corais* (ca. 125 cm total length) eating an adult *Micrurus fulvius fulvius* (ca. 75 cm total length), a semifossorial, aposematic elapid. This observation was made in a prairie hammock that is bisected by Long Bluff Road (T23S R34E NE 1/4 Sec 22) at Tosohatchee State Reserve, Orange Co., Florida, USA. When discovered, both snakes were in the road (unpaved and lightly traveled) and the *D. corais* had already captured the coral snake. The *D. corais* had ingested the head and several centimeters of the body of the *M. fulvius*, and the latter writhed alongside the body of its attacker. Six minutes of observation followed from a distance of ca. 5 m. At 1002 h, the *D. corais* elevated its head from the ground and, with its prey approximately half ingested, moved off the road. At 1005 h, consumption of the coral snake concluded and the indigo snake retreated into the hollow stump of a tree.

Submitted by **M. SHANE BELSON**, Florida Department of Environmental Protection, Tosohatchee State Reserve, 3365 Taylor Creek Road, Christmas, Florida 32709, USA (e-mail: matthec@ix.netcom.com).

MICRURUS CIRCINALIS (Trinidad Northern Coral Snake). **ARBOREALITY**. On 17 March 1999 in Arima Valley, Trinidad (10°41.57'N, 61°17.28'W), just after midnight, I observed an adult (total length ca. 40 cm) *Micrurus circinalis* 2.75 m above the ground climbing upwards on a vertical tree trunk (76 cm diam) covered with vines and aerial roots. The snake clung to the roots and bark with some determination and required several tries with a snake hook to remove it from the trunk. This is the first report of arboreal behavior in *M. circinalis*. Arboreality in *Micrurus* has previously been reported for only two species: *M. nigrocinctus* (Schmidt and Smith 1943. Publ. Field Mus. Nat. Hist., Zool. Ser. 12:129–134.) and *M. fulvius* (Carr 1994. A Naturalist in Florida: A Celebration of Eden. Yale University Press, New Haven, Connecticut. 264 pp.).

I thank Joel Friesch for his assistance in the field.

Submitted by **RICHARD A. SAJDAK**, 4 Callingham Road, Pittsford, New York 14534, USA (e-mail: rsajdak@frontiernet.net).

MICRUROIDES EURYXANTHUS (Western Coral Snake). **ENDOPARASITES**. There are, to our knowledge, no reports of endoparasites for *Micruroides euryxanthus*. The purpose of this note is to report the presence of larval spiny-headed worms (Acanthocephala) in the body cavity of *M. euryxanthus*.

Eighty-seven *M. euryxanthus*, 80 from Arizona and seven from Sonora, México, from the herpetology collections of the University of Arizona, Tucson (UAZ) and the Natural History Museum of Los Angeles County (LACM), respectively, were examined for helminths. A mid-ventral incision was made in the body wall; organ surfaces and mesenteries in the posterior portion of the body cavity were examined visually for helminths. Oblong whitish bodies, approximately 1 mm x 3 mm, were occasionally seen and these

proved, upon microscopic examination, to be oligacanthorhynchid cystacanths. Infected snakes were: UAZ 14431, 14440, 14442, 35829, 39680, 40859, 43602, 46444. Prevalence of infection (infected snakes/sample examined x 100) was 10% for the Arizona sample; none was found in the Sonora sample. Specimens were deposited in the U.S. National Parasite Collection (USNPC), Beltsville, Maryland, as USNPC 88779.

Oligacanthorhynchid cystacanths are known to occur in a variety of United States *Crotalus* (Bolette 1997a. J. Parasitol. 83:751–752; Bolette 1997b. Southwest. Nat. 42:232–236; Goldberg and Bursey 1999. Herpetol. Rev. 30:44–45) as well as colubrid snakes and teiid lizards (see Bolette 1997b. *op. cit.*). *Micruroides euryxanthus* appears to be a paratenic (transport) host for oligacanthorhynchid cystacanths. To date, there have been no reports of oligacanthorhynchid cystacanths from the two other species of coral snakes found in the United States, *Micrurus fulvius* and *Micrurus tener*. The presence of oligacanthorhynchid cystacanths in *M. euryxanthus* is a new host record.

We thank Robert L. Bezy (Natural History Museum of Los Angeles County) and Charles H. Lowe (University of Arizona) for permission to examine specimens.

Submitted by **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu), and **CHARLES R. BURSEY**, Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA.

THAMNOPHIS VALIDUS CELANO (Baja California Garter Snake). **DIET**. *Thamnophis validus celano* (sensu deQueiroz and Lawson 1994. Biol. J. Linn. Soc. 53:209–229) is endemic to the Cape Region of Baja California Sur, Mexico. This species is a known predator of *Bufo punctatus* (Blazquez 1996. Herpetol. Rev. 27:83–84; Conant 1969. Bull. Amer. Mus. Nat. Hist. 142:1–140) and the small fish *Mugil brasiliensis* (Van Denburgh 1895. Proc. California Acad. Sci. 5:77–162.). On 27 August 1996 at El Chorro, 2 km west of Aguas Calientes, I observed a *T. v. celano* (423 mm SVL) on a floating mass of vegetation eating a *Scaphiopus couchii* (54 mm SVL) vent first. This is the first record of *T. v. celano* preying on *S. couchii*.

Submitted by **JESSE L. GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

ILLINOIS SNAKES. YOUNG-OF-YEAR MORPHOLOGY AND FOOD HABITS. Little is known of the natural history of neonatal snakes from the time of hatching or birth until they begin hibernation (i.e., young-of-year = YOY) in temperate regions such as Illinois (Smith 1961. Bull. Illinois Nat. Hist. Surv. 28:1–298). Studies of food habits for snakes in Illinois involve older snakes (e.g., Klimstra 1959a. Herpetologica 15:1–5; Klimstra 1959b. Copeia 1959:210–214). Here, I report on food habits of YOY eastern garter snakes (*Thamnophis sirtalis sirtalis*), eastern hognose snakes (*Heterodon platirhinos*), blue racers (*Coluber constrictor foxii*), and prairie king snakes (*Lampropeltis calligaster*), all collected in Madison Co., Illinois, USA, during 1997 and 1998. These are the first details on YOY snakes of these species for Illinois.

All snakes were caught in pitfall traps (5-gal buckets) placed along drift fences (25 cm tall aluminum flashing). At each site visit, air temperature and soil temperature was measured to nearest degree. Pitfall traps were checked daily from 18 February 1997 to 31 October 1998. Fences were removed at the end of October 1998. All snakes greater than 400 mm SVL or not clearly identifiable as YOY (see Smith 1961, *op. cit.*) were excluded.

I measured SVL, tail length (to 1 mm), and mass (Ohaus model LS 200 portable scale to 0.1 g) for each snake. Snakes were forced to regurgitate food items, which were also weighed. Snake body mass was determined after regurgitation for snakes that regurgitated food items. All snakes were then uniquely marked by scale clipping and released. Snake handling was completed in the field at the time of capture. All vertebrate food items were preserved and deposited in the collections of the Illinois Natural History Survey (INHS 741, 742, 14508, 14474–14477).

Statistical tests were performed with SAS (SAS Institute 1996. SAS/STAT User's Guide, Statistical Analysis Systems Institute, Inc., Cary, North Carolina). I used analysis of covariance (ANCOVA) to compare least squares means (LSM) for body mass among species with SVL as the covariate. Slopes differed significantly among species ($F_{3, 23} = 15.76$, $P < 0.0001$) so I used a model for heterogeneous slopes. In the text, LSM are given ± one standard error.

Overall, 31 individual YOY snakes were captured (Table 1): 15 in 1997 and 16 in 1998. Thus, YOY snakes were equally common in both years. Most of the snakes caught were *Coluber constrictor* (N = 21).

One species differed significantly from the other three in relative weight per SVL ($P < 0.0005$). YOY *Heterodon platirhinos* (LSM = 29.4 ± 1.14 g) were relatively heavier (all pairwise comparisons $P < 0.0001$) than *Coluber constrictor* (10.2 ± 0.37 g), *Lampropeltis calligaster* (11.6 ± 1.03 g), and *Thamnophis sirtalis* (6.4 ± 2.77 g). The other three species did not differ in body mass LSM ($P > 0.09$).

Food items were found for three of the four species. One *Heterodon platirhinos* (217 mm SVL, 10.6 g) regurgitated a fresh 34 mm SVL, 5.2 g Fowler's toad (*Bufo woodhousii fowleri*). One *Lampropeltis calligaster* (340 mm SVL, 17.4 g) regurgitated two least shrews (*Cryptotis parva*), one of which weighed 5.5 g and the other 4.6 g. Food items were not found for *Thamnophis sirtalis*.

Three *Coluber constrictor* regurgitated food items. One of the snakes was 328 mm SVL and weighed 14.1 g. It regurgitated a field cricket (*Gryllus* sp.) that weighed 0.4 g. The other two *C. constrictor* reguritated YOY six-lined racerunners (*Cnemidophorus sexlineatus*). One of the *C. constrictor* (325 mm SVL, 14.8 g) contained a single *C. sexlineatus* (50 mm SVL, 2.8 g). The other *C. constrictor* (305 mm SVL, 10.3 g) had consumed three *C. sexlineatus* (40, 42, and 41 mm SVL; 1.6, 2.1, and 2.0 g, respectively).

Excepting the *Coluber constrictor* that contained the cricket, all snakes with food items contained relatively large meals. As a percentage of body mass, food item mass ranged from 20% (for one *C. constrictor*) to 58% (the *Lampropeltis calligaster*) of body mass of the snake post-regurgitation.

Environmental conditions that each species were found in were all broadly similar (Table 1). Generally rainfall was absent (0 ml in 1997, and 7.5 ml in 1998). *Coluber constrictor* tended to be

TABLE 1. Body size and mass (mean ± SD [range]) for young-of-the-year specimens of four species of snakes from west-central Illinois. First and last dates of collection are reported as month-day.

	Coluber constrictor	*Heterodon platirhinos*	*Lampropeltis calligaster*	*Thamnophis sirtalis*

caught on warmer days (Table 1, mean air temperature). However, the small sample sizes of the other species made meaningful statistical comparisons impossible. Moreover, even though average air temperature was highest for *C. constrictor*, one individual was caught on 9 November which was the last date any YOY snake was caught during the study.

The data could be affected by trapping methodology. The pitfall traps also caught potential prey items along with snakes. Thus, snakes could have preyed on items that were caught in the pits with them. Nonetheless, these snakes did eat the items observed indicating that the food items are potential acceptable prey for these YOY snakes. Moreover, on eight other occasions YOY *Coluber constrictor* were found in pits containing living, uneaten YOY *Cnemidophorus sexlineatus*. Two of the four *C. sexlineatus* found as food items had been previously marked and released at pits more than 200 m from the pit in which the snake was eventually captured. This suggests that the snake may have consumed the lizards elsewhere before capture.

The food items that I found among these YOY snakes are prey that have been widely reported in the diets of older snakes of the same species in Illinois (Klimstra 1959a, *op. cit.*; Smith, *op. cit.*) and elsewhere (e.g., Fitch 1958. Univ. Kansas Mus. Nat. Hist. Publ. 11:11–62; Mitchell 1994. The Reptiles of Virginia. Smithsonian Institution Press, Washington, D.C. 352 pp.; Palmer and Braswell 1995. Reptiles of North Carolina. University of North Carolina Press, Chapel Hill, North Carolina. 412 pp.). What is interesting is the relatively large mass of the meals that these YOY snakes are able to consume. If early growth is important in determining survivorship (e.g., Ford and Seigel 1994. Funct. Ecol. 8:91–96), then such large meals may be important to YOY snakes. I note that smaller items may be missed where snakes are not dissected (Klimstra 1959a, b, *op. cit.*). However, I tried to induce regurgitation for snakes whose bodies were not obviously distended to induce regurgitation of small food items such as the cricket noted above.

I thank M. M. Tucker for assistance in the field. The shrews were identified by J. E. Hofmann (Illinois Natural History Survey). Collecting was done under Illinois Department of Natural Resources permit number A-93.0202 and extensions. This research was supported in part by a grant from the Illinois Department of Transportation and by the Illinois Natural History Survey and the Upper Mississippi River System Long Term Resource Monitoring Program.

Submitted by **JOHN K. TUCKER**, Great Rivers Field Station, Illinois Natural History Survey, 8450 Montclaire Avenue, Brighton, Illinois 62012, USA (e-mail: John_K_Tucker@usgs.gov).

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: MINNESOTA: Aitkin Co: Savanna Portage State Park (46°50'N, 93°10'W). 11 May 1999. Gary S. Casper. JFBM 14159. Carlton Co: Nemadji State Forest, (46°25'N, 92°20'W). 4 May 1999. Gary S. Casper. JFBM 14161. Mille Lacs Co: Mille Lacs Kathio State Park (46°07'N, 93°42'W). 11 May 1999. Jeff LeClere. JFBM 14194. Pine Co: St. Croix State Forest (46°05'N, 92°28'W). 5 May 1999. Gary S. Casper. JFBM 14160. Specimens consist of females collected at nest sites, typically attending 20–30 eggs. Nests were often located in sphagnum hummocks at bases of alder (*Alnus* sp.) shrubs in shallow wetlands. Surrounding forests consisted of mixed hardwoods (*Acer* sp., *Betula* sp., *Populus* sp., and *Quercus* sp.). All specimens were verified by Tony Gamble and deposited at the James Ford Bell Museum of Natural History, University of Minnesota (JFBM). These specimens represent new county records and are the first records since the initial documentation of *Hemidactylium* in Minnesota (Dorff 1995, Herpetol. Rev. 26:150). The Minnesota records now represent the most northwestern distribution limits for this species, and are apparently not significantly disjunct from Wisconsin populations (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Mus., Milwaukee, Wisconsin. 87 pp.).

ANURA

APARASPHENODON BRUNOI. BRAZIL: BAHIA: Una (15°18'S, 39°05'W), Estação Experimental Lemos Maia (CEPLAC/ESMAI). 17 November 1990. A. J. S. Argôlo, R. Nunes, and M. de Menezes. Coleção Zoológica Gregório Bondar of the Centro de Pesquisas do Cacau, Ilhéus, Bahia (CZGB 928–29). Verified by José Perez Pombal, Jr. One specimen was found at night in the cavity of a tree trunk near a pond. Species was previously known from the states of São Paulo, Rio de Janeiro, Minas Gerais, and Espírito Santo, the latter its northermost record (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.). First record from northeastern Brazil; confirms the occurence of the species in the state of Bahia, as speculated by Sazima and Cardoso (1980, Iheringia Sér. Zool. 55:3–7).

Submitted by **ANTONIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz—UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil.

BATRACHYLA ANTARTANDICA. ARGENTINA: CHUBUT: DEPARTAMENTO RÍO SENGUER: Land between La Plata and La Plata Chico lakes, 72°00'S, 44°48'50"W, ca. 1000 m elev. 12 January 2000. C. Úbeda. Adult male (SVL 32.3 mm). Museo de Ciencias Naturales de La Plata, Buenos Aires (MLP A. 740). Verified by Néstor G. Basso. Specimen was collected in temperate humid deciduous austral beech forest of lenga (*Nothofagus pumilio*). Species inhabits austral forests of Chile and Argentina, with a narrow distribution on the eastern slopes of the Andes. This voucher represents a new record for the province of Chubut and extends known range of species in Argentina ca. 417 km airline S from previously cited localities at the Nahuel Huapi National Park in the Neuquén and Río Negro provinces (Cei 1980, Amphibians of Argentina, Monit. Zool. Ital. (N.S.), Monogr. 2:i–xii + 1–609). Specimen was found in axillar amplex within a small pool in a forest clearing (1.5 m diam. and about 1 m deep), along with several *B. antartandica* tadpoles. The area is also inhabited by *Pleurodema thaul* and *Bufo variegatus*.

Submitted by **CARMEN A. ÚBEDA**, Centro Regional Bariloche, Universidad Nacional del Comahue, Unidad Postal Universidad, R 8400 FRF Bariloche, Prov. de Río Negro, Argentina.

BUFO DIVERGENS (Crested Toad). MALAYSIA: PENINSULAR MALAYSIA: Terengganu: Lata Belatan, on forest floor, 20 m from lower waterfalls (5°37'N, 102°35'E, ca. 75 m elev.). 25 December 1999. Tzi Ming Leong. Raffles Museum of Biodiversity Zoological Reference Collection (ZRC.1.3669, adult female with pigmented ova, 38.8 mm SVL). Verified by Kelvin K. P. Lim. Confirms literature record (Berry 1975, The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp.); constitutes first voucher specimen for the Malay Peninsula and represents the northernmost extent of its range there. Within peninsular Malaysia, *B. divergens* has been reported from only two other localities: Selangor (Boulenger 1912, A Vertebrate Fauna of the Malay Peninsula from the Isthmus of Kra to Singapore Including the Adjacent Islands. Reptilia and Batrachia. Taylor and Francis, London. xiii + 294 pp.) and at Ulu Kinchin, Pahang (Lim 1990, Malaysia Nat. J. 43:322–325). This species also occurs in Borneo (Brunei, Kalimantan, Sabah, and Sarawak), Sumatra, and the Natuna Islands (Inger and Tan 1996, Raffles Bull. Zool. 44:551–574).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-mail: tziming@hotmail.com).

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: FLORIDA: ST. JOHNS CO: Anastasia Island, Fort Matanzas National Monument (29°42'56.3"N, 81°13'59.3"W). 12 December 1998. K. L. Krysko and F. W. King. Verified by M. A. Nickerson. UF 116160-61. New county record; collected near buildings in maritime forest.

Submitted by **KENNETH L. KRYSKO** (e-mail: kenneyk@flmnh.ufl.edu) and **F. WAYNE KING** (e-mail: kaiman@flmnh.ufl.edu), Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA.

HYLA ANCEPS. BRAZIL: BAHIA: Pau Brasil, Fazenda Água Santa (15°27'S, 39°37'W). 25 November 1997. J. Abade da Silva and A. J. S. Argôlo. Coleção Zoológica Gregório Bondar of the Centro de Pesquisas do Cacau, Ilhéus, Bahia (CZGB 1651). Collected at night over leaves on the border of a stream. Previously known from the states of Rio de Janeiro, where the type locality is located (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.), Espírito Santo (Haddad et al. 1985, Herpetol. Rev. 26:207) and Minas Gerais (Nascimento and Feio 1999, Herpetol. Rev. 30:49–50). First record from the state of Bahia and from northeastern Brazil.

Submitted by **ANTONIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz—UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil.

HYLA CINEREA (Green Treefrog). USA: TEXAS: POLK CO: Big Sandy Creek Unit, Big Thicket National Preserve, 900 m NE jct. Fire Tower Road and FM 943. 20 May 1999. Stephen D. Lewis and John D. Quine. Stephen F. Austin State University (SFA 4897). Verified by Fred L. Rainwater. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

MELANOPHRYNISCUS STELZNERI STELZNERI. ARGENTINA: LA RIOJA: Patquía (30°03'S, 66°53'W). 26 January 1935. A. Breyer. Herpetological Collection, Museo Argentino e Instituto de Investigación de las Ciencias Naturales "Bernardino Rivadavia", Buenos Aires, Argentina (MACN 1178, two specimens). Verified by Gustavo Carrizo. First province record; nearest previous records were Cordoba and San Luis (Cei 1980, Mon. Zool. Ital. Mus. Reg. Sci. Nat. Torino. 609 pp.; Gallardo 1987, Librería Agropecuaria. 98 pp.; Gallardo y Varela de Olmedo 1992, Fauna de Agua Dulce de la República Argentina. Vol 21. Amphibia I. 114 pp.).

Submitted by **JORGE ABEL CESPEDEZ**, Cátedra de Anatomía Comparada, Departamento de Biología, Facultad de Ciencias Exactas y Naturales, Universidad Nacional del Nordeste, 9 de julio 1449, Caixa Postal 3400, Corrientes, Argentina (e-mail: cespedez@exa.unne.edu.ar).

MICROHYLA PETRIGENA (Pothole Narrowmouth Frog). INDONESIA: EAST KALIMANTAN: Kayan basin, Sungai Panan (tributary of Sungai Iwan), small potholes on rocky bank of river (02°00'44"N, 115°03'34"E, 530 m elev.). 25 November 1999. Heok Hui Tan. Raffles Museum of Biodiversity Research Zoological Reference Collection (ZRC.1.3780–3826, 47 larvae, with one Stage 43 larva, total length 16 mm, exhibiting characteristics diagnostic of adults of the species). Verified by Kelvin K. P. Lim. New country record; confirms postulation of its probable occurrence in Kalimantan (Inger and Stuebing 1997, A Field Guide to the Frogs of Borneo. Natural History Publications, Kota Kinabalu, Sabah, Malaysia. ix + 205 pp.).

Submitted by **TZI MING LEONG** and **HEOK HUI TAN**, Department of Biological Sciences, National University of Singapore, Singapore 119260.

RANA CAPITO (Gopher Frog). USA: GEORGIA: TAYLOR CO: isolated depressional wetland ca. 4 km WNW jct. Georgia Rt. 96 and Georgia Rt. 137 (exact locality withheld due to sensitivity of species). 25 February 1997. John B. Jensen. Georgia Museum of Natural History (GMNH 44320). Verified by M. E. McGhee. Several egg masses observed and one male found calling while submerged. First county record (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712).

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

RANA CATESBEIANA (Bullfrog). USA: COLORADO: FREMONT CO: Thizizit Ranch, 6701 Co. Rd. 19, 11 km SSE Florence. 20 June 1998. Richard L. Holland. UCM 59962. Verified by Kyle Ashton. First County record (Livo et al. 1997, Herpetological microbiogeography of Colorado II: Documented and potential county records: 1997 Interim summary. Publ. Colorado Herpetological Society. 25 pp.) and the westernmost record of the species on the eastern side of the continental divide in Colorado. The rancher, Charles Francis, stated that Bullfrogs have been present at the site throughout the five years of his ownership.

Submitted by **RICHARD L. HOLLAND** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA.

RANA SYLVATICA (Wood Frog). USA: TENNESSEE: JACKSON CO: Dodson Branch, NE of Hidden Springs Nursery on Spring Creek Road at the base of Dodson Branch (36°19'20"N, 85°30'42"W). 9 October 1999. Priya Nanjappa. Austin Peay State University Museum of Zoology (APSU 5283 [color slide]). Verified by A. Floyd Scott. Adult captured in leaf litter in a mixed forest near Dodson Branch; photographed and released. New county record (Redmond and Scott 1996, Austin Peay St. Univ. Misc. Publ. 12:1–94).

Submitted by **PRIYA NANJAPPA** and **LAURA LEININGER**, Muncie Center for Medical Education, Ball State University, Muncie, Indiana 47306, USA.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). USA: MASSACHUSETTS: FRANKLIN CO: Sunderland, jct. North Plain Road and Plum Tree Road. 8 July 1999. UMA A0895, adult female. Verified by Nathan J. Kley. Confirmation of an historic county record. Franklin County represents the northernmost limit of the species in the Connecticut River Valley of New England. Species was first collected in Franklin County by R. Wood in 1952 (UMA A0455). The specimen reported herein represents the first definitive evidence of the occurrence this species in Franklin County since 1952.

Submitted by **MARK MANDICA**, Department of Biology, University of Massachusetts, Amherst, Massachusetts 01003, USA, (e-mail: winhold@student.umass.edu) and **ALAN RICHMOND**, Department of Biology, University of Massachusetts, Amherst, Masssachusetts 01003, USA (e-mail: alanr@bio.umass.edu).

TESTUDINES

ACANTHOCHELYS SPIXII (Spinyneck Swamp Turtle). ARGENTINA: CORRIENTES: Saladas Department: 35 km N San Roque on National Highway 12; ca. 65 masl (28°16'46"S, 58°41'34" W—Datum: WGS84). 11 April 1999. T. Waller, M. D. Beccaceci, and P. A. Micucci. Museo Argentino de Ciencias Naturales "Bernardino Rivadavia" (MACN 37083). Verified by Gustavo Carrizo. In Argentina, this species is known from only three localities along the eastern banks of the Paraná river in Corrientes Province (Cabrera 1995, Ann. Mus. Hist. Nat. Valparaiso 23:41–52). Fourth and easternmost locality for species in Argentina and a new departmental record for Corrientes Province.

DEIROCHELYS RETICULARIA (Chicken Turtle). USA: FLORIDA: FRANKLIN CO: St. Vincent National Wildlife Refuge, AOR jct. Windmill Road and Road G, E end of island. 8 January 2000. Terry Peacock. KU Color Slides 11768–770; AOR jct. Dune Road and Road B. 12 January 2000. Thom Lewis. KU Color Slides 11771–773. Photographs by Suzanne L. Collins. Both verified by Joseph T. Collins; ca. 100 m ENE jct Roads B and D. 20 February 2000. Thom Lewis. Clemson University Vertebrate Collection (CUSC 1898). Verified by Kelly J. Irwin. Skeletal remains consisting of disarticulated carapace and intact plastron, with few as-

sociated scutes. First island records (Blaney 1971, Herpetologica 27:406–430).

Submitted by **TERRY PEACOCK** and **THOMAS E. LEWIS**, St. Vincent National Wildlife Refuge, P.O. Box 447, Apalachicola, Florida 32329, USA.

DEIROCHELYS RETICULARIA MIARIA (Western Chicken Turtle) USA: TEXAS: Hill Co: Adult female found crossing I-35, 16.9 km S Hillsboro exit (jct. Rts. 77 and 81), 7.2 km S FM 1242. 0930 h. 7 June 1986. William B. Montgomery. KU Color Slide 11670. Verified by John E. Simmons. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **WILLIAM B. MONTGOMERY**, P.O. Box 656, Elgin, Texas 78621, USA.

DEIROCHELYS RETICULARIA RETICULARIA (Eastern Chicken Turtle). USA: VIRGINIA: Isle of Wight Co: 3.5 km NE Chuckatuck, Cat Pond ephemeral pond complex. 16 April 1999. Michael W. McCoy. KU Color Slides 11745–749. Verified by Don Schwab and Alan H. Savitzky. First record for county. Adult female (213 mm carapace length, 184 mm plastron length, body mass 1301 g) captured in pitfall trap adjacent to an ephemeral pond. Seven additional specimens subsequently were captured at this site. Extends range 53 km west of only other record of this species in Virginia. Formerly species was recorded only from one locality in the city of Virginia Beach, believed to be an introduced or isolated disjunct population (Mitchell 1994, The Reptiles of Virginia. Smithsonian Inst. Press, Washington, D.C. xv + 352 pp.). This record raises the probability that additional populations of this species may occur in southeastern Virginia and northeastern North Carolina.

Submitted by **MICHAEL W. McCOY** and **DONALD J. SCHWAB**, Virginia Department of Game and Inland Fisheries, Wildlife Diversity Division, Nongame and Endangered Wildlife Program, 5806 Mooretown Road, Williamsburg, Virginia 23188, USA, and **ALAN H. SAVITZKY**, Department of Biological Sciences, Old Dominion University, Norfolk, Virginia 23529-0266, USA.

MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle). USA: TEXAS: Nacogdoches Co: Stephen F. Austin Experimental Forest (31°29'N, 94°47'W), Bonaldo Creek. 27 April 1999. Christopher S. Collins. Color slides SFAT1–4. Verified by Michael B. Keck. New county record. (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M Univ. Press, College Station. 434 pp.) An 11.5 kg female caught in a 4-foot diameter hoop net (Texas Permit Number SPR-0490-059) during an Alligator Snapping Turtle survey.

MANOURIA IMPRESSA (Impressed Tortoise). CAMBODIA: Province of Stung Treng: Siem Pang. 16 January 2000. Edgar Lehr and Rohan Holloway. Staatliches Museum für Tierkunde, Dresden (MTKDD 42504). Verified by Uwe Fritz. First country record. Previously known from neighboring countries (Moll 1989, *Manouria impressa*, Impressed Tortoise. Pp. 121–122 in Swingland and Klemens (eds.), The Conservation Biology of Tortoises. Occ. Pap. IUCN Species Survival Commission No. 5). Specimen (shell) was bought from an animal hunter in Veurn Sai (Province of Ratanakiri), who claimed to have caught it in the mountains north of Siem Pang.

Submitted by **EDGAR LEHR**, Forschungsinstitut und Naturmuseum Senckenberg, Senckenberganlage 25, D-60325 Frankfurt a. M., Germany (e-mail: elehr@sng.uni-frankfurt.de), and **ROHAN HOLLOWAY**, Applied Ecology Research Group, University of Canberra, ACT 2601, Australia (e-mail: rohanholloway@hotmail.com).

PALEA STEINDACHNERI (Wattleneck Softshell). CHINA: YUNNAN: Hekou Autonomous County. 30 July 1975. Jiang Yaoming. Chengdu Institute of Biology (CIB 755201). Verified by J. R. Buskirk. First confirmed record for the province; extends the geographic range of the species ca.110 km westward (Iverson 1997, A Revised Checklist with Distribution Maps of the Turtles of the World. Green Nature Books, Homestead, Florida). There are striking differences between the distributions of Chinese turtles as reported by Iverson (1997, *op. cit.*) and Chinese herpetologists (Tian et al. 1986, Identification Manual for Chinese Amphibians and Reptiles. Science Press, Beijing [in Chinese]; Zhao and Adler 1993, Herpetology of China. SSAR, Oxford, Ohio). This is largely attributable to the relative inaccessibility of the Chinese literature and its lack of vouchered localities. For example, although not reported in Iverson (1997, *op. cit.*), *P. steindachneri* is known from two localities in southern Guizhou Province (Bangzha near Xingyi and Wangme; Wu et al. 1985, The Reptile Fauna of Guizhou. Guizhou People's Publishing House, Guiyang [in Chinese]). In addition to Guichou Province and the provinces listed by Iverson (1997), Tiang et al. (1986, *op. cit.*) and Zhao and Adler (1993, *op. cit.*) list *P. steindachneri* as occurring in Guangdong and Yunnan provinces, but do not give references, detailed localities, or vouchers. The specimen reported herein establishes the presence of this turtle in the Yuan Jiang/Song Hong river of Yunnan Province.

Submitted by **JAMES FORD PARHAM**, Department of Integrative Biology, University of California, Berkeley, California 94720-3140, USA (e-mail: parham@socrates.berkeley.edu) and **YUEZHAO WANG**, Chengdu Institute of Biology, Chengdu, Sichuan, 610041 People's Republic of China (e-mail: arcib@mail.cib.ac.cn).

STERNOTHERUS MINOR (Loggerhead Musk Turtle). USA: ALABAMA: Marion Co: 16 km E Hamilton, Buttahatchee River at U.S. Rt. 278 (34°08.211'N, 87°52.159'W). 26 March 1998. T. J. Near and R. S. Steinberg. Verified by C. A. Phillips. INHS 13961. New county record (Mount 1975, The Reptiles and Amphibians of Alabama. Auburn University Agricultural Experiment Station, Auburn, Alabama. 347 pp.).

Submitted by **JOHN E. PETZING** and **THOMAS J. NEAR**, Illinois Natural History Survey, Center for Biodiversity, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

LACERTILIA

ANOLIS CAROLINENSIS (Green Anole). TEXAS: KARNES CO: ca. 2.5 km ENE Runge city limits near jct. Texas Rt. 72 and Co. Road 322, Larry Dement Ranch near Ojo de Agua Creek. 10 April 1999. Valerie Shafer. Stephen F. Austin State University (SFA 4900). Verified by Michael Keck. First record for county (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **VALERIE SHAFER**, Department of Biology, P.O. Box 13003, Stephen F. Austin State University, Nacogdoches, Texas 75962, USA; e-mail: z_shafervm@ titan.sfasu.edu.

BARISIA IMBRICATA CILIARIS (Northern Imbricate Alligator Lizard). MEXICO: CHIHUAHUA: under large oak log in Mesa de Agostadero, Cerro Blanco, Municipio Balleza, Km 102, Guachochi-Balleza Highway (26°54'38.7"N, 106°47'14.1"W), 235 masl. 26 July 1999. Julio A. Lemos-Espinal. Unidad de Biotecnología y Prototipas (UBIPRO 3034). Verified by Richard L. Holland. First precise record for the state of Chihuahua (Good 1988, Univ. California Publ. Zool. 121:80), although two previous records for unspecified localities in the state, all probably referable to *B. levicollis*, were noted by Guillette and Smith (1982, Trans. Kansas Acad. Sci. 85:32). Moreover, literature records (*loc. cit.* and Van Devender and Lowe 1977, J. Herpetol. 11:43) for Sierra del Nido are in error and actually are *B. levicollis*. Specimen reported herein is a northward range extension of about 125 km from Guanacevi, Durango (Guillette and Smith 1982, *op. cit.*).

BOGERTIA LUTZAE. BRAZIL: BAHIA: Trancoso (16°39'S, 39°06'W). 25 November 1999. D. Vrcibradic and F. H. Hatano. Museu Nacional, Rio de Janeiro (MNRJ 7581–2); Prado (17°18'S, 39°13'W). 29–30 November 1999. C. F. D. Rocha, M. Van Sluys, F. H. Hatano and D. Vrcibradic. MNRJ 7583–6. Verified by M. T. Rodrigues. All individuals were collected among bromeliad leaves in open coastal sand-dune habitats ("restingas"). This little-known gekkonid lizard was, until recently, known only from a locality in the state of Pernambuco (Igarassu, 7°50'S, 34°54'W) and from Salvador (12°50'S, 38°25'W) in the state of Bahia (Vanzolini and Gomes 1979, Pap. Avulsos Zool. São Paulo 32:254). Rodrigues (1987, Arq. Zool. São Paulo 31:223–224) mentions the occurrence of this species in Cumuruxatiba (17°06'S, 39°11'W) in the state of Bahia, without citing vouchers. He commented that geckos from this locality were found in undisturbed rainforest habitat, unlike those of Salvador and Igarassu, which were recorded in restinga habitats. He suggested that his population may have been historically isolated from its congeners in Salvador, some 500 km away, due to a gradual rising of sea-level (which presumably altered previously favorable habitats south of Salvador, forcing the geckos to adapt to a different habitat). Conversely, our findings of populations of *B. lutzae* in coastal restinga habitats, both close to Cumuruxatiba and to the north of it, are suggestive that the distribution of this lizard may actually be fairly continuous along the coast of Bahia (at least from Salvador southward). The specimens here mentioned constitute the first vouchers reported from south of Salvador. Prado lies about 30 km south of Cumuruxatiba and is therefore the southernmost locality recorded for *B. lutzae*.

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **DONALD S. SIAS** and **LELAND J. S. PIERCE**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

EUMECES OBSOLETUS (Great Plains Skink). USA: NEW MEXICO: Harding Co: Kiowa National Grasslands, along upper reaches of Cañon Mesteño, ca. 11.3 km airline N and 11.1 km airline W jct. New Mexico Rt. 120 and New Mexico Rt. 39 at Roy, NE 1/4 Sec. 19, T21N, R25E (36°02.818'N, 104°18.634'W). 25 June 1999. Leland J. S. Pierce. University of New Mexico Museum of Southwestern Biology (MSB 61481). Verified by W. G. Degenhardt. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **LELAND J. S. PIERCE**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

HEMIDACTYLUS MABOUIA (Tropical Gecko). HONDURAS: COLÓN: Trujillo (15°55'N, 85°57'W), near sea level on wall of house in town. June 1998. Elizabeth Wilson. USNM 536064. Verified by R. Powell. First record for country for this introduced species; closest reported localities are the Los Tuxtlas region, Veracruz, México (Powell et al. 1998, Cat. Amer. Amph. Rept. 674.1–674.11) and the Canal Zone, Panamá (Auth 1994, Publ. Smithson. Herpetol. Inform. Serv. 98:1–59). The Honduran locality lies ca. 1000 km airline ESE of the Mexican locality and ca. 975 km airline NW of the Panamanian locality.

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157, USA, and **LARRY DAVID WILSON**, Department of Biology, Miami-Dade Community College, Kendall Campus, Miami, Florida 33176, USA (e-mail: lwilson@mdcc.edu).

OPHISAURUS ATTENUATUS ATTENUATUS (Western Slender Glass Lizard). USA: TEXAS: Bastrop Co: 90 m W jct. Sayers Road and Rt. 95, 11.5 km S Rt. 290. 16 May 1991. William B. Montgomery. KU Color Slide 11671. Verified by John E. Simmons. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **WILLIAM B. MONTGOMERY**, P.O. Box 656, Elgin, Texas 78621, USA.

SCELOPORUS MAGISTER (Desert Spiny Lizard). USA: NEW MEXICO: Lincoln Co: White Sands Missile Range, 15 mi W Oscuro at Wood gravel pit off Range Road 12. NW 1/4 Sec 35, T9N, R7E. 17 August 1999. D. W. Burkett and D. Black. Verified by C. W. Painter. University of New Mexico Museum Southwestern Biology (MSB 61419). County record (Degenhardt et al. 1996, The Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **DOUGLAS W. BURKETT** and **DAVID BLACK**, MEVATEC Corporation, P.O. Box 399, White Sands Missile Range, New Mexico 88002, USA.

UTA STANSBURIANA (Side-blotched Lizard). USA: NEW MEXICO: Lincoln Co: White Sands Missile Range, 15 mi W Oscuro at Wood gravel pit off Range Road 12. NW 1/4 Sec 35, T9N, R7E. 21 August 1999. D. W. Burkett and D. Black. Verified by C. W. Painter. University of New Mexico Museum Southwestern Biology (MSB 61418). County record (Degenhardt et al. 1996, The Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **DOUGLAS W. BURKETT** and **DAVID BLACK**, MEVATEC Corporation, P.O. Box 399, White Sands Missile Range, New Mexico 88002, USA.

SERPENTES

CROTALUS LEPIDUS LEPIDUS (Mottled Rock Rattlesnake). MEXICO: CHIHUAHUA: mountain near La Perla (= El Berrendo), Municipio Camargo (28°17'59.8"N, 104°33'5.0"W). 4 July 1999. Julio A. Lemos-Espinal. Unidad de Biotecnología y Prototipos, Universidad Nacional Autónoma de México (IBIPRO 3896). Verified by Richard L. Holland. First precise locality of record in the state of Chihuahua, although expected on the basis of general range (Gloyd 1940, Chicago Acad. Sci. Spec. Publ. 4:1–270; Klauber 1972, Rattlesnakes. Univ. California Press, Berkeley. 2 vols.). Extends range slightly farther west than hypothesized by Klauber (*op. cit.*).

Submitted by **JULIO A. LEMOS-ESPINAL**, Laboratorio de Ecología, Unidad de Biotecnología y Prototipos, Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autónoma de México, Apartado Postal 314, Avenida de los Barrios s/n. Los Reyes Iztacala, Tlalnepantla, Estado de México, 54090 México, and **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA.

CROTALUS LEPIDUS MACULOSUS (Durangan Rock Rattlesnake). MEXICO: JALISCO: Volcán de Tequila, Municipio de Tequila, 2840 m (20°48'N, 103°51'W). 1 August 1999. Héctor and Rodolfo Romero Contreras. Universidad Autónoma de Guadalajara, México (UAGM R-425). Verified by H. M. Smith. New state record (Tanner et. al. 1972, Great Basin Nat. 32:16–24).

Submitted by **PAULINO PONCE-CAMPOS**, **RODOLFO ROMERO-CONTRERAS**, and **SARA M. HUERTA-ORTEGA**, Bosque Tropical, A. C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México.

DIADOPHIS PUNCTATUS (Ringneck Snake). USA: ARIZONA: Coconino Co: Walnut Canyon National Monument, picnic area rest rooms, 2042 m. 25 August 1973. Scott Archer. Flagstaff Area National Monuments collection (WACA 3029). Apache Co: Malpais (= Cave) Spring, SW of St. Johns, SW 1/4 NE 1/4 Sec. 26, T12N, R26E, 1884 m. Collected under rock beside marsh, along with a *Thamnophis elegans*. 2 June 1989. C. H. Lowe and G. L. Bradley. UAZ 48343. Both verified by Phil Rosen. First records for both Coconino and Apache counties, and first records for eastern Arizona north of the Mogollon Rim (Fowlie 1965, Snakes of Arizona. McGraw Hill, Inc., New York; Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Second Ed. Houghton Mifflin Co., Boston, Massachusetts). Extends range ca. 69 km NNE and 71 km NNE from nearest records in Yavapai and Navajo counties, respectively (Fowlie, *op. cit.*).

Submitted by **TREVOR B. PERSONS**, Forest and Rangeland Ecosystem Science Center, Colorado Plateau Field Station, Box 5614, Northern Arizona University, Flagstaff, Arizona 86011, USA,

and **GEORGE L. BRADLEY**, Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, Arizona 85721, USA.

ENHYDRIS ENHYDRIS (Rainbow Water Snake). MALAYSIA: PENINSULAR MALAYSIA: PULAU TIOMAN: Sungai Paya mangroves (02°48'N, 104°08'E). 22 June 1999. Heok Hui Tan. Raffles Museum of Biodiversity Research Zoological Reference Collection (ZRC.2.4593, adult, SVL 435 mm, tail 103 mm, fresh wt. 64.0 g; liver tissue sample deposited FMNH). Verified by Kelvin K. P. Lim. New island record; second species of genus from island; *E. plumbea* recorded previously (Lim and Lim 1999, Raffles Bull. Zool. Suppl. No. 6:131–155).

Submitted by **TZI MING LEONG** and **HEOK HUI TAN**, Department of Biological Sciences, National University of Singapore, Singapore 119260.

LAMPROPELTIS TRIANGULUM ELAPSOIDES (Scarlet Kingsnake). USA: FLORIDA: FRANKLIN CO: St. George Island, 817 East Gorrie Drive. 15 May 1999. M. B. Capron and J. A. Capron. Verified by Richard Montanucci. Clemson University Vertebrate Collection (CUSC 1845). Adult found DOR in residentially developed coastal dune habitat. First record for St. George Island and Apalachicola Bay Barrier Islands (Blaney 1971, Herpetologica 27:406–430; Means 1974, *In* Livingston et al. [eds.], St. George Island: Biota, Ecology, and Management Program for Controlled Development. Rept. Develop. Regional Impact Franklin County Commission).

Submitted by **KELLY J. IRWIN**, 1618 Davis Creek Road, Seneca, South Carolina 29678, USA, and **MARTIN B. CAPRON** and **JILL A. CAPRON**, 1832 East 20th North Avenue, Oxford, Kansas 67119, USA.

LEPTOTYPHLOPS DULCIS DISSECTUS (New Mexico Blind Snake). USA: NEW MEXICO: MORA CO: Kiowa National Grasslands, Unit 91 along Canadian River, ca. 9.7 air km N and 15.3 air km W jct. New Mexico Rt. 120 and New Mexico Rt. 39 at Roy, SW 1/4 Sec. 23, T21N, R24E. 22 June 1999. Don S. Sias. University of New Mexico Museum of Southwestern Biology (MSB 61478). Verified by W. G. Degenhardt. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **DONALD S. SIAS** and **LELAND J. S. PIERCE**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

LEPTOTYPHLOPS HUMILIS (Western Blind Snake). USA: NEW MEXICO: LINCOLN CO: White Sands Missile Range, 15 mi W Oscuro at Wood gravel pit off Range Road 12. NW 1/4 Sec 35, T9N R7E. 7 September 1999. D. W. Burkett and D. Black. University of New Mexico Museum Southwestern Biology (MSB 61414); OTERO CO: White Sands Missile Range, 14 mi W Three Rivers. Specimen caught in pitfall bucket in Malpais Lava Flow. SE 1/4 Sec 16, T12N, R7E. 17 August 1999. D. W. Burkett and D. Black. MSB 61415. Both verified by C. W. Painter. County records (Degenhardt et al. 1996, The Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **DOUGLAS W. BURKETT** and **DAVID BLACK**, MEVATEC Corporation, P.O. Box 399, White Sands Missile Range, New Mexico 88002, USA.

MICRURUS DISTANS ZWEIFELI (Zweifel's Coral Snake). MEXICO: AGUASCALIENTES: Río Gil, municipality Calvillo (21°52'48"N, 102°37'47"W). 21 May 1994. Gustavo Quintero-Díaz and Joel Vázquez-Díaz. Museo de Zoología, Departamento de Biología, Universidad Autónoma de Aguascalientes (UAA-VR 253); 1 km S Milpillas de Arriba, Calvillo (21°58'39"W, 102°33'12"W). 1 November 1997. Rigoberto Gómez-Torres. UAA-VR 269; 1 km SE La Labor, municipality Calvillo (21°58'15"N, 102°42'07"W). 13 August 1998. Gilfredo de la Riva-Hernández. UAA-VR 278. All in subtropical scrub and verified by Fernando Mendoza-Quijano. First record for the state of Aguascalientes; extends range 185 km NE Magdalena, Jalisco (Roze 1961, Amer. Mus. Novitates 2287:1–60).

Submitted by **GUSTAVO QUINTERO-DIAZ**, Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, Avenida Universidad 940, Aguascalientes, Aguascalientes 20100, México, **JOEL VAZQUEZ-DIAZ**, Departamento de Investigación y Desarollo Tecnológico, Internacional de Relojes, Arte y Diseño S. A. de C. V., Avenida Aguascalientes Sur 203, Fracc. Prados del Sur, Aguascalientes, Aguascalientes 20280, México, and **HOBART M. SMITH**, Department of EPO Biology and Museum, University of Colorado, Boulder, Colorado 80309-0334, USA.

OPHEODRYS AESTIVUS (Rough Green Snake). USA: KENTUCKY: CAMPBELL CO: California, 5 km N on Rt. 8, Thomas More College Ohio River Biology Field Station (38°57'31"N, 84°17'50"W). June 1996. Adam Mann. Thomas More College (TMC R5). Verified by C. Lorentz. New county record; first voucher specimen (Meade 1993, Doctoral Dissertation, Univ. Southern Mississippi. 608 pp.).

Submitted by **ADAM MANN**, **MELISSA R. OBERMEYER**, and **JOHN W. FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA.

RHINOCHEILUS LECONTEI (Longnose Snake). USA: NEW MEXICO: LINCOLN CO: White Sands Missile Range, 13 mi W Oscuro on Range Road 12. SW 1/4 Sec 26, T9N, R7W. 17 June 1999. D. W. Burkett and D. Black. Verified by C. W. Painter. University of New Mexico Museum Southwestern Biology (MSB 61421). County record (Degenhardt et al. 1996, The Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **DOUGLAS W. BURKETT** and **DAVID BLACK**, MEVATEC Corporation, P.O. Box 399, White Sands Missile Range, New Mexico 88002, USA.

SALVADORA GRAHAMIAE (Mountain Patchnose Snake). USA: NEW MEXICO: HARDING CO: Kiowa National Grasslands, along Cañon Mesteño, ca. 1.1 km airline upstream jct. Canadian River and ca. 14.5 km airline NW Roy, 36°00.165'N, 104°20.083'W. 23 June 1999. Charles W. Painter. University of New Mexico Museum of Southwestern Biology (MSB 61480). Verified by W. G.

Degenhardt. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.). An adult female of this species was observed, but not collected, near this site on 28 May 1989 (T. L. Brown, pers. comm.).

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **DONALD S. SIAS**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

TANTILLA BOCOURTI BOCOURTI (Bocourt's Blackhead Snake). MEXICO: NAYARIT: Sierra de Alicia, Bajio de las Palas, Municipio de La Yesca (21°45'N, 104°24'W), 2000 m elev. 20 July 1996. Paulino Ponce-Campos. Universidad Autónoma de Guadalajara, México (UAGM R419 a–b, two photographs). Verified by Hobart M. Smith. First record for mainland Nayarit, although species is known from Maria Cleofas Island (McDiarmid et al. 1976, Los Angeles Co. Mus. Nat. Hist. Contrib. Sci. 275:1–17).

Submitted by **PAULINO PONCE-CAMPOS** and **SARA M. HUERTA-ORTEGA**. Bosque Tropical, A. C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México.

TANTILLA MELANOCEPHALA. ARGENTINA: CORRIENTES: SANTO TOMÉ DEPARTMENT: Estancia San Pedro (28°09'S, 56°42'W). 27 December 1997. R. H. Aguirre and E. F. Schaefer. Herpetological collection of Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC 6763, a female 231 mm SVL, 59 mm TL). Verified by A. Giraudo. Second province record with precise locality; extends range ca. 128 km airline east from the previous record in Mburucuyá National Park (Montanelli and Alvarez 1998, Herpetol. Rev. 29:179). Species was reported as ranging from Central America to northern Argentina (Peters and Orejas Miranda 1970, Bull. U.S. Nat. Mus. 297:295). In Argentina, it was reported without voucher specimens from Chaco, Corrientes, and Misiones provinces (Koslowsky 1898, Rev. Mus. La Plata 8:197, Serié P; 1921, Ann. Soc. Científ. Argentina 92:165, Serié P; 1936, Int. Mus. Univ. Nac. La Plata. Obra Cincuent.; Abalos and Mischis 1975, Bol. Acad. Nac. Cien. Córdoba 51[1-2]:72), and with a voucher in Entre Ríos province (Vuoto 1998, Mus. Cienc. Nat. y Antrop. "Prof. Antonio Serrano" Paraná, Entre Ríos, Argentina. Serie Vertebrados: Los Reptiles [6]:12 pp.).

Submitted by **EDUARDO FEDERICO SCHAEFER** and **BLANCA BEATRIZ ALVAREZ**, Cátedra de Anatomía Comparada, Departamento de Biología, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de julio 1449, 3400 Corrientes, Argentina (e-mail: efs@exa.unne.edu.ar).

TANTILLITA LINTONI (Linton's Dwarf Short-tailed Snake). BELIZE: TOLEDO DISTRICT: Belize Foundation for Research and Environmental Education, ca. 10 km NE Medina Bank Village (16°31'N, 88°40'W). 15 August 1997. Jacob A. Marlin. Verified by Julian C. Lee. Campbell Museum, Clemson University, Clemson, South Carolina (CUSC 1613). Second specimen from Belize; extends distribution within Toledo District ca. 51 km NE of earlier record near San Jose Village (Lee 1996, The Amphibians and Reptiles of the Yucatan Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.).

Submitted by **STEVEN G. PLATT**, Wildlife Conservation Society, P.O. Box 1620, Phnom Penh, Cambodia, **JACOB A. MARLIN**, Belize Foundation for Research and Environmental Education, P.O. Box 129, Punta Gorda, Belize, Central America, and **THOMAS R. RAINWATER**, Lamanai Field Research Center, P.O. Box 63, Orange Walk Town, Belize, Central America.

Louisville, Kentucky 40292, USA

**Corresponding author; e-mail: perri.eason@louisville.edu*

Generalized Kentucky distributions for many reptiles and amphibians have been previously documented (Barbour 1971). However, for many species specific distributional data are lacking, especially for the counties of northern Kentucky, also known as the Bluegrass Region (MacGregor et al. 1997; MacGregor, unpubl. data). We here document 29 new county records for amphibians and reptiles in northern Kentucky (USA). Kentucky Educational Wildlife Collecting Permits were obtained to collect reptiles and amphibians for this distribution survey. All specimens were deposited at the University of Louisville Museum (UL), and were verified by Peter Sherman. Common names are those standardized by Collins (1997).

Eurycea cirrigera (Southern Two-lined Salamander). ROBERTSON CO: Road 617, stream running alongside road, N38.27.860, W84.05.415. 11 June 1998. O. Attum and B. Attum. UL 10013. HENRY CO: McMannis Road, N38.33.407, W85.07.777. 30 August 1998. O. Attum and B. Attum. UL 10019.

Eurycea lucifuga (Cave Salamander). HARRISON CO: 237 Moore's Mill Road, N38.32.358, W84.12.854. 12 July 1998. O. Attum and B. Attum. UL 10038.

Plethodon glutinosus (Slimy Salamander). ROBERTSON CO: Blue Lick State Park under debris at campground. 11 June 1998. O. Attum and B. Attum. UL 10014.

Acris crepitans blanchardi (Blanchard's Cricket Frog). ROBERTSON CO: Road 539, N38.32.181, W84.03.770. 17 July 1998. O. Attum and B. Attum. UL 10039.

Bufo americanus (American Toad). BRACKEN CO: Road 19, N38.32.244, W84.10.033. 17 June 1998. O. Attum and B. Attum. UL 10028. ROBERTSON CO: Blue Lick State Park. Parking Lot, N38.26.294, W83.59.790. 11 June 1998. O. Attum and B. Attum. UL 10011. DOR. HARRISON CO: Havelandsville Road, N38.34.665, W84.14.033. 12 July 1998. O. Attum and B. Attum. UL 10020.

CARROL CO: General Butler State Park campground. 8 August 1998. UL 10024.

Bufo woodhousii fowleri (Fowler's Toad). HENRY CO: McMannis Road, N38.33.408, W85.07.777. 30 August 1998. O. Attum and B. Attum. UL 10021. CARROL CO: Buffalo Creek Road, N38.37.433, W85.02.464. 28 August 1998. UL 10025. HARRISON CO: Havelandsville Road, N38.34.474, W84.16.087. 12 July 1998. O. Attum and B. Attum. UL 10036.

Hyla versicolor/chrysoscelis complex (Gray Treefrog). ROBERTSON CO: Road 539, N38.32.786, W84.04.574. 17 June 1998. O. Attum and B. Attum. UL 10018. HARRISON CO: Havelandsville Road, N38.34.474, W84.16.087. 12 July 1998. O. Attum and B. Attum. UL 10037.

Rana catesbeiana (Bullfrog). ROBERTSON CO: Road 539, N38.32.181, W84.03.770. 17 June 1998. O. Attum and B. Attum. UL 10029. HENRY CO: Road 574, N38.31.859, W85.11.016. 30 August 1998. O. Attum and B. Attum. UL 10031. Tadpole.

Rana clamitans melanota (Green Frog). HENRY CO: McMannis Road, N38.33.407, W85.07.777. 30 August 1998. O. Attum and B. Attum. UL 10030. ROBERTSON CO: Road 539, N38.32.786, W84.04.574. 17 June 1998. O. Attum and B. Attum. UL 10017. GALLATIN CO: Goulds Road, N38.43.139 ,W84.56.997. 13 September 1998. O. Attum and B. Attum. UL 10023. DOR.

Chelydra serpentina (Common Snapping Turtle). ROBERTSON CO: BlueLick State Park, road leading to "future developments." 23 May 1998. O. Attum and B. Attum. UL 10035.

Terrapene carolina carolina (Eastern Box Turtle). ROBERTSON CO: Road 617, N 38.27.860, W84.05.415. 11 June 1998. O. Attum and B. Attum. UL 10026. Trampled by cattle. HARRISON CO: Havelandsville Road, N38.34.474, W84.16.087. 17 June 1998. O. Attum and B. Attum. UL 10027. DOR. CARROL CO: Gilgal Road, N38.36.978, W85.08.47. 13 September 1998. O. Attum and B. Attum. UL 10022. DOR.

Coluber constrictor constrictor (Black Racer). ROBERTSON CO: Blue Lick State Park entrance road, N38.26.294, W83.59.790. 11 June 1998. O. Attum and B. Attum. UL 10012. DOR.

Diadophis punctatus edwardsii (Northern Ringneck Snake). ROBERTSON CO: Blue Lick State Park under trash can behind cottages. 11 June 1998. O. Attum and B. Attum. UL 10034.

Elaphe obsoleta obsoleta (Black Rat Snake). ROBERTSON CO: Road 3196, N38.31.153, W84.07.289. 11 June 1998. O. Attum and B. Attum. UL 10010. DOR.

Lampropeltis triangulum triangulum. (Eastern Milk Snake). BRACKEN CO: Road 62, N38.30.081, W84.12.775. 17 June 1998. O. Attum and B. Attum. UL 10033. DOR. ROBERTSON CO: Road 617, N38.32.786, W84.04.574. 12 July 1998. O. Attum and B. Attum. UL 10015. DOR.

Regina septemvittata (Queen Snake). ROBERTSON CO: Road 617, N38.32.860, W84.05.415. 11 June 1998. O. Attum and B. Attum. UL 10016.

Thamnophis sirtalis sirtalis (Eastern Garter Snake). HARRISON CO: Road 27 South, N38.32.382, W84.17.180. 12 July 1998. O. Attum and B. Attum. UL 10032. DOR.

Acknowledgments.—We thank John MacGregor and Robert E. Todd for their courtesy and assistance in the preparation of this manuscript.

We have compiled the following records from Hardee County in the central Florida (USA) peninsula, based on Ashton (1988). All specimens have been deposited in the Florida Museum of Natural History, University of Florida, Gainesville (UF), and all are new county records. Common names are those standardized by Collins (1997).

Siren lacertina (Greater Siren). SE 1/4 Sec. 7, T35S, R24E. 6 June 1998. C. A. Young. Verified by D. Auth. UF 115607–610.

Pseudobranchus axanthus (Southern Dwarf Siren). SE 1/4 Sec. 7, T35S, R24E. 6 June 1998. C. A. Young. Verified by P. Moler. UF 115613–614.

Recent field work on the western Highland Rim of central Tennessee, USA, has yielded several new county records and one substantial range extension for the state's herpetofauna. Most of these records, presented below, are from the contiguous counties of Houston and Humphreys, which border the east shore of Kentucky Lake (Tennessee River) between River Miles 74 and 118. One record is from the flood plain of the Cumberland River in Cheatham County. Records for amphibians were considered new if the species in question was not reported from a given county by Redmond and Scott (1996) or in literature having appeared since. Turtle records were deemed new based on a general search of the literature and range maps in Ernst et al. (1994), Mount (1975), Iverson (1977, 1992), Pritchard (1989), Lovich (1993), and Conant and Collins (1998). All collections were made by one or more of the authors and documented with photographs and/or voucher specimens deposited in the Austin Peay State University Museum of Zoology (APSU). Identifications were verified by David H. Snyder. Nomenclature and common names follow Collins (1997).

Ambystoma opacum (Marbled Salamander). HOUSTON CO: 150 m N of Billy Parchman Road at Tennessee Rt. 46, 10 km NE of Erin (36°22'01"N, 87°35'42"W). 21 November 1999. APSU 6056 (alcohol specimen). Adult found under rock near base of shallow forested ravine. New county record that fills gap between records in Dickson and Benton counties.

Ambystoma tigrinum (Eastern Tiger Salamander). HOUSTON CO: ca. 0.5 km SE of intersection of Old Tennessee Rt. 49 and Sine Road, 6.9 km SE of Erin (36°17'30"N, 87°37'31"W). 12 October 1999. APSU 5494 (alcohol specimen). One adult male under log among dead trees in abandoned hog lot, ca. 100 m from nearest pond. New county record.

Eurycea lucifuga (Cave Salamander). HOUSTON CO: Unnamed cave entrance along Brigham Branch, ca. 1.0 km upstream from confluence with Wells Creek, 3.5 km SE of Erin (36°20'45"N, 87°40'32"W). 13 October 1999. APSU 5495 (alcohol specimens). Two specimens collected from 17 observed around cave entrance. New county record.

Siren intermedia nettingi (Western Lesser Siren). CHEATHAM CO: flood plain of Cumberland River at River Mile 155, ca. 150 m N of Chapmansboro Road (36°17'56"N, 87°07'01"W). 22 March 1999. APSU 1678 (alcohol specimen). Two specimens taken from a palustrine wetland with emergent vegetation. New county record

that fills gap along Cumberland River between records from Montgomery and Davidson counties.

Bufo fowleri (Fowler's Toad). HOUSTON CO: Cedar Valley Road, 1.0 km S of Tennessee Rt. 49, 5.6 km SE Erin (36°17'47"N, 87°38'28"W). 1 September 1999. APSU 6051 (alcohol specimen). Juvenile found under rotting log in small wood lot. New county record that fills gap among records from five surrounding counties.

Gastrophryne carolinensis (Eastern Narrowmouth Toad). HOUSTON CO: Cedar Valley Road, 1.0 km S of Tennessee Rt. 49, 5.6 km SE Erin (36°17'47"N, 87°38'28"W). 1 September 1999. APSU 6052 (alcohol specimen). Adult female found under rotting log in small wood lot. New county record that fills gap among records from five surrounding counties.

Acris crepitans blanchardi (Blanchard's Cricket Frog). HOUSTON CO: Sine Road, 1.1 km W of Old Tennessee Rt. 49, 6.0 km SE Erin (36°17'35"N, 87°38'08"W). 28 August 1999. APSU 6045 (alcohol specimen). One specimen taken from child's swimming pool; others heard in nearby ponds. New county record that fills gap among records from five surrounding counties.

Hyla cinerea (Green Treefrog). HOUSTON CO: East side of Kentucky Lake (Tennessee River) at back of Whiteoak Creek Bay, River Mile 81 (36°15'34"N, 87°53'36"W). 20 June 1999. APSU 6046 (alcohol specimen). Adult male found in buttonbush (*Cephalanthus occidentalis*) over water near shore; several others calling in vicinity. HUMPHREYS CO: Bakerville Road along outer edge of W flood plain of Buffalo River, 0.4 km S of Miller Road (35°58'53"N, 87°22'23"W). 5 June 1999. Adult male on road adjacent to palustrine wetland where others of the species were calling. APSU 6031 (alcohol specimen). New county records, the latter being the most upstream site for the species along Kentucky Lake.

Hyla chrysoscelis/versicolor complex (Cope's Gray Treefrog/Eastern Gray Treefrog). HOUSTON CO: Sine Road, 1.1 km W of Old Tennessee Rt. 49, 6.0 km SE Erin (36°17'35"N, 87°38'08"W). 24 August 1999. APSU 1396 (alcohol specimen). One specimen taken from child's swimming pool; others heard in nearby ponds. HUMPHREYS CO: Bakerville Road along outer edge of W flood plain of Buffalo River, 0.4 km S of Miller Road (35°58'53"N, 87°22'23"W). 5 June 1999. Adult male on road adjacent to palustrine wetland where others of the species were calling. APSU 6035 (alcohol specimen). New county records that fill N–S gap between Montgomery and Perry counties.

Pseudacris feriarum (Upland Chorus Frog). HOUSTON CO: 150 m N of Billy Parchman Road at a point 1.9 km NE of jct. with Tennessee Rt. 46, 10 km NE of Erin (36°22'01"N, 87°35'42"W). 21 November 1999. APSU 6047 (alcohol specimen). One specimen taken on a foggy morning (1100 h) from a fern glade (clump of *Polystichuma crostichoides*) near base of shallow, forested ravine; several others calling nearby, along with numerous *Pseudacris crucifer*. New county record that fills gap between Stewart and Humphreys counties.

Rana sphenocephala utricularius (Southern Leopard Frog). HOUSTON CO: 7.0 km SE of Erin, midway between Sine and Wolf Pit roads (35°58'53"N, 87°22'23"W). 6 September 1999. APSU 6055 (alcohol specimen). One juvenile individual captured at nearly dry farm pond; many others of the species present. New county record that fills gap among records from five surrounding counties.

Macroclemys temminckii (Alligator Snapping Turtle). HOUSTON CO: back of Whiteoak Creek Bay on East side of Kentucky Lake (Tennessee River) at River Mile 81 (36°15'18"N, 87°53'03"W). 31 December 1995. APSU 5526 (color slide). Adult male (midline carapace length 534 mm, plastron length 640 mm, preanal tail length 275 mm, weight 58.7 kg). Captured after it was discovered eating a freshly killed mallard duck; released at capture site after being measured, weighed, photographed, and fitted with a radio transmitter. Four other adult individuals (1 male and 3 females) have been documented from the lower Whiteoak Creek area since this discovery, the latest in June 1999. New county record that fills gap in distribution along the Tennessee River between records from Stewart and Humphreys counties.

Sternotherus minor peltifer (Stripeneck Musk Turtle). HOUSTON CO: lower Whiteoak Creek, 0.5 km downstream from Whiteoak Road bridge (Magnolia Bridge) (35°15'30"N, 87°52'30"W). 11 June 1999. APSU 6049 (color slide). Adult male (carapace length 90 mm, plastron length 53 mm) taken with dip net over firm mud substrate at depth of 1 m. Two additional individuals, one a juvenile (carapace length 53 mm, plastron length 33 mm), the other an adult female (carapace length 91 mm, plastron length 66 mm) captured and released at the same locality a few days later. These records come from an area that is ca. 160 km N of the nearest known population in Lauderdale County, Alabama (Mount 1975), and represent the only records for this species below Pickwick Dam in the Tennessee River drainage.

I am a herpetologist in a small museum sitting at the cold end of a hot continent that's noted for neither its infrastructure nor its surplus finance. As such the Facsimile Reprint series of the SSAR is a godsend. The title page of this volume, the first to be devoted to African herpetology, notes that it was produced in cooperation with the Herpetological Association of Africa. This is generous, for in truth the finance and publishing support were wholly SSAR, and I take this opportunity to thank them for their magnificent service, in this and other instances, to the herpetological community.

Schmidt and Noble's reviews of the *Herpetology of the Belgian Congo* (here jointly abbreviated to HBC) were originally published separately in the *Bulletin of the American Museum of Natural History*. The reptiles were reviewed by Karl P. Schmidt and appeared in two parts; Part 1 – Turtles, crocodiles, lizards and chameleons in vol. 39 (1919), and Part 2 – Snakes in vol. 49 (1923). These were followed by G. K. Noble's review of the amphibians (vol. 49, 1924). All issues have long been out of print, although the *AMNH Bulletin* is well known and not too difficult to obtain via normal library services. Therefore, the commitment of the SSAR to collating these contributions into a facsimile reprint cannot have been based on any great inaccessibility of the originals. Not, at least to European and American researchers. Rather, it seems to reflect a growing appreciation of the neglect of African herpetology, and the desire of the SSAR to stimulate interest in a unique herpetofauna. In keeping with their other recent facsimiles, SSAR has invited leading authorities (Don Broadley, reptiles; J. C. Poynton, amphibians) to review and update the taxonomy of the work, and to present updated checklists and biographic notes on the authors.

Most of the material that forms the basis of HBC was collected during the AMNH Congo expedition. This was the longest and largest colonial expedition to the "Dark Continent," and it lasted for six years (1909–1915) and covered nearly 15,000 miles, mostly on foot or by canoe (for details see Osborn 1919). This expedition yielded over 4000 herpetological specimens. For the most part the journey passed through colonial "Belgian Congo," subsequently Zaïre and more recently the Democratic Republic of the Congo (DRC). Both Schmidt and Noble, however, used the extensive HBC collections as a base from which to review existing knowledge of the regional herpetofauna. Neither took part in the prolonged field work. This fell under the control of Herbert Lang, who was later to undertake other important expeditions on the continent (e.g., the 1930 Vernay Lang Kalahari expedition).

Studying the HBC collection was the young Schmidt's first appointment, undertaken as a temporary assignment when he was only 26 and still an undergraduate student at Cornell University. Possibly stimulated by the excellent field notes and photographs of Lang, Schmidt brought a fresh approach to the HBC that resulted in it becoming one of the first modern treatments of a herpetofauna. Species became ecological components of their landscape, and not simply typical specimens and taxonomic constructs. It was a revolutionary integration of ecology and taxonomy, and reflected the movement away from the 19th century museum-based taxonomic treatise. It heralded a herpetology driven by field work and the awareness of biogeographic realms and ecological processes.

This approach was not obvious in the work of European or African museum scientists at the time, or even later. In Africa, Arthur Loveridge (Harvard) collected detailed natural history notes during his numerous African expeditions, but was rarely deflected from his monographic systematic reviews. Similarly, Vivian FitzSimons (Pretoria) also failed to embrace this new approach, which was surprising given his involvement in the Vernay Lang Kalahari expedition. In fact, in the past century, J. C. Poynton was the most notable student to use his taxonomic studies as a basis for detailed zoogeographic analysis of African amphibians. For reptiles, however, Schmidt's preliminary studies, including his simple maps of African lizard and snake distributions, remained the only overview attempted during the 20th century. Fortunately both Broadley and Poynton are currently involved in studies to redress this situation.

Schmidt commented (p. 391) on "... the vital influence of the plant distribution in determining that of African animals". In effect, he recognized the obvious division into savannah and forest biota, with the result that "Lines of equal rainfall, and not isotherms, are the chief climatic factors in African distribution." Schmidt was, like most herpetologists of his era, based in a northern temperate climate. Reviewers from tropical habitats, more familiar with the dominance of wet and dry seasons on the distribution and activity of faunas, would have been less surprised.

Given the era and its colonial perspective, it may surprise some readers to discover just how modern many of Schmidt's comments remain; e.g., "...it is possible that the genera *Coleonyx, Eublepharis, Hemitheconyx* and *Holodactylus* will be found to form a natural (monophyletic) group among the simpler geckos..." (p. 16). Knowledge of the Cordylidae (Zonuridae) was still formative at the time, with only seven *Cordylus,* three *Chamaesaura*, three or four *Platysaurus* and a single *Pseudocordylus* species known. Despite this, Schmidt corrected Cope's description of *Zonurus (= Cordylus) tropidosternum* from Madagascar, and was aware that the family was characteristically Afrotropical (Ethiopian) and had its evolutionary epicenter (was 'entogeneic') in the subcontinent (p. 18). It is an observation that has been subsequently refined by Mouton and Van Wyk (1997).

Obviously, in the intervening eight decades since Schmidt's reviews appeared, some of his conclusions have been challenged. Although he doubted that the webbed feet of *Palmatogecko* were suitable for burrowing (p. 16), Haacke (1976), among others, has

described in detail the daily burrow excavation of this beautiful gecko. Similarly, the distribution map (p. 25) for *Aporosaura anchietae* (= *Meroles*), then known from only a few specimens, extends too far north and too far inland. It is endemic to the shifting dunes of the Namib Desert (Branch 1998).

Broadley's admirable introduction to Schmidt's reviews gives an update of the taxonomic status of names discussed by Schmidt, the first reptile checklist for the country, as well as a bibliography of post-1963 herpetological literature for the DRC (the earlier period is detailed in Laurent 1965). A number of recent taxonomic changes affect Broadley's DRC checklist, most initiated by himself. He recently revived *Python natalensis* as a southern species (Broadley 1999), with probable sympatry occurring in Kenya, Tanzania, and Kiva Province (DRC). Similarly, *Elapsoidea boulengeri* was also validated as a full species (Broadley 1997), and enters extreme eastern Kiva Province (Tipoyo), although this was not noted by Broadley in his regional breakdown of the DRC herpetofauna. The remaining DRC records of *E. semiannulata* (from the southern, western, and central regions) are referable to *E. s. moebiusi* (Broadley 1997), which itself may best be regarded as an allopatric, phylogenetic species.

The races of other polytypic species, e.g., the *Mabuya striata* complex and *Thelotornis capensis*, are also to be treated as a suite of sibling, phylogenetic species (Broadley, pers. comm, October 1999), and this approach has been adopted in other parts of the checklist; e.g., *Rhinotyphlops mucruso*, which was previously treated as a race of *R. schlegelii* (Roux-Estève 1974). Hughes (1997) has indicated that *Dasypeltis atra* may occur in Eastern DRC, and also noted that southern and eastern African populations of the brown house snake, commonly referred to *Lamprophis fuliginosus*, may better be referred to *L. capensis* (Duméril and Bibron 1854). The status of populations of brown house snakes in southern DRC remains unresolved. The tree agama genus *Acanthocercus* is misspelled (as *Acanthocerus*), but this is my fault as it simply perpetuates a mistake occasioned by my poor proofing of various publications (e.g., Branch 1998).

At the time of Noble's review of HBC amphibians very little comparative African material existed in American museums. Noble therefore completely reviewed African amphibian literature, and "in order that this work may not be lost" appended both a detailed bibliography and a checklist of all African amphibians to his HBC review. For many years these remained the main summaries of the African Amphibia. The incorporation of Lang's detailed habitat notes, supplemented with stomach content details, added greatly to the biological value of Noble's review. Based on details from *The Phylogeny of the Salientia* (Noble 1922), the introductory sections for each family contained summaries of their phylogeny, distribution, and content. They still serve as useful historical summaries.

Although Noble did not discuss caecilians, several species are now known from the DRC and adjacent regions, and Poynton lists three species in his checklist. To these may be added a fourth—in a recent paper Nussbaum and Pfender (1998) added *Schistometopum thomense* to the DRC herpetofauna.

Noble, like so many subsequent workers despaired with hyperoliids: "In no genus of frogs are there so many undefinable, intergrading species as in *Hyperolius*. It is the most dominant tree frog in Africa and yet systematically it is the most unsatisfactory" (p. 250). Little has changed, and the state of hyperoliid systematics remains chaotic, despite fragmentary insight from the detailed field work of Schiøtz in the north and Channing in the south. It is, therefore, not surprising that there are numerous differences among Noble's treatment of hyperoliids, that in Poynton's checklist, and that in the recent review of African tree frogs by Arne Schiøtz (1999). The latter provisionally treats *Afrixalus upembae* (Laurent 1941) as a valid taxon; it is not included in Poynton's checklist, where it was presumably subsumed under *A. fulvovittatus* (of which it was originally described as a southern race). Poynton follows Laurent (1972) in treating Noble's *H. langi* as a race of *H. platyceps*. However, Schiøtz (1999) continues to recognize *H. langi*, albeit noting that "The status of this form is not clear." He also considers the single DRC record of *H. bolifambae* to be doubtful. The status of many of Laurent's (1943, 1951, 1964 and 1979) other DRC *Hyperolius* (e.g. *H. ferrugineus, H. ghesquieri, H. inornatus, H. obscurus, H. polli, H. polystictus, H. robustus., H. sankuruensis, H. vilhenai, H. leleupi* and *H. xenorhinus*), many of which remain known only from the types (described from single specimens or small samples from single localities), remains problematic. Resolution will depend on detailed fieldwork in a region of continued political strife and collapsed infrastructure. Poynton suggests that *Hyperolius acutirostris* and *H. pardalis* both occur in the western region of DRC, but this is conjecture as they are currently known only from Cameroon (Schiøtz 1999).

Like Broadley, Poynton has included a comprehensive updated bibliography in his contribution. I noted only one relevant title overlooked—Nussbaum and Hinkel (1994).

When they first appeared, Schmidt and Noble's reviews formed essential references, even for herpetologists working in northern and southern Africa. With the updated systematics, and appended bibliographies and checklists of Broadley and Poynton, their value is enhanced. This well-produced, strongly-bound, and aesthetically-pleasing SSAR facsimile reprint is a must for all herpetologists interested in the African fauna.

University of California, Santa Barbara, California 93106-9610, USA
e-mail: sweet@lifesci.ucsb.edu

Billed as an update of *Goanna, the Biology of Varanid Lizards* (1993), *Monitors* is in fact a limited revision. While remaining true to the original structure and emphases, the text has been refined or expanded throughout to reflect additions to the literature through mid-1999. This has been done very carefully indeed, and few if any significant citations have been overlooked. Unfortunately, the production schedule did not enable the incorporation of work published in the proceedings of the second international varanid conference (Horn and Bohme 1999), though there are brief references to some of the findings reported there.

Most of the revisions in this volume are relatively minor, and are evident only by direct comparison with the original version. The principal augmentations are a short section on foraging behavior, and a new chapter on endo- and exoparasites. Since the original edition was not widely available outside of Australia, there is merit in this conservative approach, but if you have the original edition the case for acquiring this revision is not as strong as it might be.

The book's stated aim is to interpret the research literature on the biology of varanids in a form accessible to the general public. It succeeds at this level, being both more comprehensive and more accurate than are other recent semitechnical books on monitors. The thematic thread is a focus on the biology of *Varanus rosenbergi*, which has been the subject of considerable physiological and ecological research by the authors. With the exception of some newly-reported information on the behavior of hatchling *V. rosenbergi*, these sections are essentially unchanged. The bulk of the new material thus consists of brief entries describing new work with other species. This has been faithfully done throughout the book's 11 chapters (on phylogeny, feeding, breeding, general behavior, thermal biology, respiration, water balance, energetics, parasites, and conservation and management).

Individual chapters generally provide enough introductory material to guide the non-specialist reader, but will be on the cusp of value to individuals already familiar with the topics. The presentation is more often descriptive and enumerative than analytical, commonly with general statements being followed by a parenthetical listing of species known to conform, and little further. The result is that a reader would often like to know more. This is sometimes provided under another subheading elsewhere in the book, but seldom with the linkages necessary to appreciate how the features are interrelated.

In my view, the strictly topical format is unforgiving. By partitioning the coverage, the opportunities to present an integrated outlook are orphaned for lack of the appropriate categories. Integration is most conspicuously absent at two levels: there is no formal coverage of the species diversity of varanids beyond a list in one table, and there is scant consideration of the roles of varanids in communities. An interested reader would have to look elsewhere for help in identifying varanids, or to learn which species might be expected in a given region; worse, the suggested readings omit all references of this sort! While it is not intended as a field guide, I do think that the book misses the mark by failing to provide an interested general reader with the means to satisfy these most basic of questions about monitors. Such a section on diversity could include much of the published information on general natural history that is presently treated in piecemeal fashion. In a similar vein, a chapter on "varanids in communities" would have provided a forum for a broader coverage of the comparative ecology of monitor lizards. Here the focus on *V. rosenbergi* as a largely allopatric, temperate-zone species cannot convey much about the excitement of the rich varanid communities of lower latitudes.

The new chapter on parasites of varanids is considerably more integrative precisely because it is comparative. It ably summarizes a considerable body of work on ticks and nematodes that is not widely known among herpetologists, but should be. In short, varanids harbor a diversity of ticks and nematodes, but with some unusual patterns both of regional occurrence and of the distribution of parasites among varanid species. This is fascinating material if you already know the ranges and ecologies of the monitor species discussed, but it will be difficult for the general reader to ascertain what the chapter conveys in the absence of a taxonomic or distributional background.

The final chapter on conservation and management stresses the potentially adverse effects of the extensive trade in varanid skins originating in Africa and southeast Asia, and documents that national and CITES regulations are widely stretched, if not flouted. This has been an issue for many years, and both the reported export volumes and the evident shifts in countries providing the largest consignments suggest that regional overharvesting is at hand.

By contrast, the Australian species are regarded as being secure, and well protected by "generally well enforced" legislation. This is surely true in the sense that Australian species do not figure into the skin trade, nor are their distributions under general pressure from habitat alienation. However, the new plates in the revision document an issue that the text does not discuss: five of the nine new photographs are of hatchlings or juveniles of Australian species that are being bred in Europe. While I cannot swear to it, I do not think that species such as *Varanus glauerti* or *V. pilbarensis* have ever been legally exported from Australia alive, yet they and most others are sold openly in Europe (and in the U.S. via European sources). This is incongruous in a book intended to foster an appreciation of the biology of varanids and an understanding of conservation issues.

The book is carefully produced, with very few typographical errors, and includes a list of suggested readings that provides an entry into the recent literature.

If you are after a balanced evaluation of this book, look elsewhere. I am not capable of providing one. Like many (most) other snake ecologists of my generation, my postgraduate years were inspired by the herculean efforts of Henry Sheldon Fitch. His monographic publications on ecological and life-history characteristics of reptiles and amphibians of the University of Kansas Natural History Reservation (now appropriately named in honor of the man himself) were virtually the only references on snake ecology available in those dim and distant days (i.e., about 30 years ago). The situation is very different today, with snakes having become popular subjects of ecological research. Part of the reason for that transition involves methodological advances (snakes are ideally suited for radiotelemetry) and a general shift in community attitudes (increasingly, snakes are seen as worth conserving and hence, worth studying)—but another strong factor was the pioneering work by Henry Fitch. It is difficult to overstate the degree to which Fitch's methodological and conceptual innovations changed the field of snake ecology.

Well into retirement, Fitch continues to break new ground. In a research field where a six or eight-year study is generally regarded as "long-term," the 50-year data sets enshrined in this book are likely to break all records for all time. As resource managers grapple with the difficulty of translating "pure" research into conservation strategies, the value of these long-term data sets is becoming increasingly apparent. Herpetological ecology is fortunate indeed to have had prophets such as Henry S. Fitch and Donald W. Tinkle, who stimulated the next generation to maintain long-term projects at their study areas. The persistence required for such efforts is considerable, especially in light of three-year funding cycles from most grant agencies.

In the case of the Fitch Reservation, one of the most important benefits of the long-term study is to document the ways in which successional changes in the system (brought about by the cessation of livestock grazing in 1950) modified the vegetation of the reserve, and thus the availability of prey species and shelter sites for particular taxa of snakes. For example, the rapid post-grazing increase in herbaceous vegetation stimulated an increase in rodent numbers and thus, the abundance of copperheads (*Agkistrodon contortrix*) over the next five years. The subsequent encroachment of woody vegetation reduced small mammal numbers, with a consequent decline not only in copperhead numbers, but also in mean adult body sizes of the snakes. Those of us who go out and sample study areas over brief periods of time, and then interpret the determinants of body sizes and abundances from such data, would do well to reflect upon the immense temporal (as well as spatial) heterogeneity detected in Fitch's study.

Fitch's book on Kansas snake communities is a richly-illustrated account of the major findings from his studies over the period 1948 to 1997. During that period, he accumulated > 32,000 capture records of 18 snake species. Some taxa were captured very frequently, whereas others were found very infrequently, or only at certain times, in certain places and by particular methods. For example, Fitch found only three western earth snakes (*Virginia valeriae*), and only one redbelly snake (*Storeria occipitomaculata*) over the entire study! These extraordinarily low capture rates convey an important message for those who use short-term surveys to assess the presence or absence of a rare species (especially to decide if the next housing development can proceed!). For the common species, Fitch assembled a remarkable data set on a wide and eclectic diversity of variables—from behavior to diet, from thermal biology to spatial ecology, from food habits to parasite loads, from reproduction to growth trajectories, and from abundance to long-term responses to the profound vegetational shifts that occurred during the study. The text is organized species-by-species, and is well illustrated with tables, graphs and photographs. The book is not simply a re-hash of Fitch's many publications on the snakes of the Reserve. Many of those papers appeared decades ago, whereas the book is based on analyses up to the present. In many cases, the additional years of study have added substantially to the overall information on these species. For example, Fitch's classic monograph on copperheads was published in 1960, but the current book includes data on this species from most years up to 1997.

The prose is clear and the writing is tight. There are no flights of poetic fancy, but one is left with a vivid impression of a man who knows these animals and their habitats with an intimacy that few people ever achieve. The book also includes abundant references to published literature on these taxa, especially with respect to the ways in which the Kansas populations differ from those of conspecifics from other areas. The encyclopedic grasp of this litera-

ture is not surprising, from the man who wrote definitive reviews of topics such as reproductive cycles and sexual size dimorphism in reptiles (1970, 1981).

The strongest comparison with Fitch's book is surely Hajime Fukada's 1992 overview of his Japanese studies, "Snake Life History in Kyoto." Like Fitch, Fukada had to deal with low levels of funding and little external recognition of the value of his science. Like Fitch, he developed many of the techniques that are in common use today in field studies on snakes. And like Fitch, his study areas changed dramatically over the course of his research, to the point that snake numbers fell so low that further work was unproductive. In the current research environment, there is substantial pressure on scientists to conduct their studies quickly, then publish and move on to the next problem. Fitch was doubtless exposed to similar pressures: his studies did not enjoy popular acclaim until long after they had begun. Today, however, there is universal agreement among snake biologists that the lessons learned on this small reservation in Kansas have played a seminal role in the scientific development of our discipline. This volume bears eloquent testimony to that role, and to the monumental accomplishments of a stubborn individualist.

Guide des Serpents et Amphisbènes de Guyane, by F. Starace. 1998. Ibis Rouge Editions, Guadeloupe, Guyane. 452 pp. Softcover, ca. US $68.00. ISBN 2-911390-27-x.

MARCIO MARTINS
Departamento de Ecologia Geral, Instituto de Biociências, Universidade de São Paulo, Caixa Postal 11461, 05422-970 São Paulo SP, Brazil
e-mail: jararaca@ib.usp.br

This new book by Fausto Starace, a French geographer, appeared about ten years after the publication of Chippaux's (1986) book on the snakes of French Guiana. It is a paperback printed on good quality paper and treats the 95 snakes and three amphisbaenians known to occur in French Guiana (although the author suggests that three more amphisbaenians and several additional snakes may also occur in the country).

The book begins with a 24-page section that illustrates and describes in detail the diverse habitats found in French Guiana. This section ends with a short text on the native people of French Guiana.

The first section is followed by a short, illustrated section in which Starace provides comments on snake classification, dentition types, and taxonomic characters used to identify snakes and amphisbaenians, and gives suggestions on how to use the book. This is followed by the 344-page section of species accounts. These in turn are followed by short sections (some detailed and interesting) on many subjects: collecting localities; snake envenomation (by V. Debons), collecting methods, biogeography, biology, behavior, biotopes and frequency of snake sightings, ethnoherpetology, legislation on conservation of reptiles of French Guiana, and a short conclusion with a review on the present knowledge of French Guianan snakes and amphisbaenians. The book terminates with a short glossary of scientific words used in the book (many of them pertaining to the vegetation), a literature cited section, an index of scientific names, and a table of contents.

Species accounts are preceded by summaries (diversity, natural history, gross morphology, and taxonomy) on the general group, family, and genus, as well as keys for identification (at all levels). Starace provides an English version for all keys (following those in French). In many keys, genera and species that the author thinks may occur in French Guiana are included, some of them very likely based on their Guyanan distribution (e.g., *Apostolepis*, *Atractus torquatus*, *Liophis poecilogyrus*, *Micrurus spixii*). Accounts of colubrids are presented in an artificial, outdated classification based solely on dentition types. This splits species from natural, monophyletic groups (e.g., snakes of the tribe Xenodontini appear both within the aglyphous and opisthoglyphous groups; e.g., *Xenodon* in the former and *Erythrolamprus* in the latter). No comment is made about recent systematic arrangements within the colubrids, and no subfamilial or tribal names are cited. Recent taxonomic changes are also omitted (e.g., *Corallus hortulanus* rather than *C. enhydris*; the genera *Taeniophalus* and *Xenoxybelis*; see review of these changes in Martins and Oliveira 1999).

In each species account Starace provides a list of synonyms, type locality, common name (none in most instances), vernacular names (including local native names in four languages, as well as Portuguese), description (only color pattern), size, sexual dimorphism, habits, diet (including effects of bites in humans), reproduction, habitat (including macrohabitat), distribution, number of specimens collected, and a short abstract in English. The accounts also include a small distribution map for French Guiana and a useful table with 13 characters based on lepidosis. At the end of each account, the author also provides a classification based on the dentition type followed by a comment on the potential danger of a bite for humans. One to five color photographs or a (generally poor) drawing of the head and neck (when no photograph is available) illustrate each account. For many species the photographs show different color morphs, ontogenetic variation in color pattern, and the venter. Most of these 179 photographs are of good quality and are very useful for identification.

The text of the species accounts is a mixture of good, substantiated data and dubious and even probably incorrect statements, especially about natural history. Original, useful data on behavior, reproduction, habitat, and microhabitat are provided in several accounts. On the other hand, original diet data are only rarely provided. Only in a few intances are references to literature containing original data cited. The author fails to provide the number of individuals on which most statements dealing with activity time, microhabitat, habitat, and diet are based.

Dubious statements about diet are especially common in the text. At least in part, Starace's statements seem to be based on unsubstantiated food records from the literature (e.g., Chippaux 1986; Cunha and Nascimento 1978, 1993; Wehekind 1955). Because the author provides neither literature citations nor specimen data that could substantiate his statements, most of the informa-

tion on diet is useless. Furthermore, in some instances the author provided apparently unsubstantiated guesses about food items. A good example is in the first account, on *Amphisbaena alba*. Starace states that its diet is composed "essentially of insects, arthropods, earthworms, and certainly of snakes of small size." What does "certainly" means in this context? Did the author find prey remains that could most probably be of a snake? Or is he just guessing that *A. alba* could eat small snakes?

To minimize the perpetuation of those putatively incorrect statements about the diet of several Amazonian snakes, I here provide a list of those that appear in Starace's book: birds and frogs in the diet of *Corallus caninus* (only mammals and lizards were found, according to Henderson 1993); lizards for *Atractus* spp. (apparently specialized on earthworms and arthropods; reviewed in Martins and Oliveira 1993; but see Chippaux 1986: Table VI); birds and mammals for *Chironius carinatus*, *C. fuscus*, *C. multiventris*, and *C. scurrulus* (all apparently specialized on amphibians and lizards; see Dixon et al. 1993; but see a record of a bird for *C. fuscus* in Beebe 1946; see also Wehekind 1955); birds and lizards for *Dendrophidion dendrophis* (a frog specialist; reviewed by Martins and Oliveira 1999); lizards for *Liophis typhlus* (apparently a frog specialist; reviewed by Martins and Oliveira 1999); mainly birds and mammals for *Siphlophis cervinus* (mainly lizards; reviewed by Prudente et al. 1998); birds for *Xenodon severus* (apparently a frog and lizard specialist; Beebe 1946; Dixon and Soini 1986; Duellman 1978; but see Cunha and Nascimento 1993); birds for *Xenoxybelis argenteus* (a frog and lizard specialist; Duellman 1978; Martins and Oliveira 1999; but see Chippaux 1986: Table VI); and birds for *Lachesis muta* (a mammal specialist; reviewed by Martins and Oliveira 1999).

Starace's book clearly is more directed to lay people than to scientists. However, despite some dubious and probably incorrect information on natural history, I recommend the book to herpetologists for the following reasons: 1) It is a very useful field guide for identification of northeastern Amazonian snakes (most species also occur in other Amazonian regions), especially because of the color photos, keys, and tables with scale counts; 2) Starace provides a large amount of good quality information on natural history (except for diet in some accounts; see above); 3) There are useful descriptions of the habitats of French Guiana, some of which characterize wide areas of northern South America.

INDRANEIL DAS

Institute of Biodiversity and Environmental Conservation
Universiti Malaysia Sarawak
94300 Kota Samarahan, Sarawak, Malaysia
e-mail: idas@mailhost.unimas.my

This book is the companion volume to *The Field Guide to the Frogs of Borneo*, written by the same team of authors (Stuebing and Inger). Given the scarcity of literature on the herpetology of Southeast Asia in general, and on snakes in particular (there had been no update on the snake fauna of the island of Borneo since De Rooij, 1917), the present work will be a great help, not only to biologists (many of them local students, without access to literature, such as the work of De Rooij, which, after all, does not include color photos), but also tourists, conservationists, and local laypeople. Technically, this is a well-produced work, in both paperback and hardcover (with dust jacket) editions, in the usual high standards of printing that characterize publications of Natural History (Borneo) Publications Sdn. Bhd. (which, apart from the frog and snake books already mentioned, have also published an introductory text on the natural history of Sabah's herpetofauna, and a reprint of the 1966 monograph to the Bornean amphibian fauna by Inger).

The front cover photograph of the snake book shows a *Trimeresurus popeorum*, the back cover illustrates a *Bungarus fasciatus*. Separate chapters include an introduction, a checklist, general aspects of snake biology, including adaptations and ecology, conservation, the relationships between snakes and humans on Borneo (which includes a small section on snake bite treatment), a field key to the species (using, whenever possible, col-

oration and other external features), and the species accounts, each typically 1–2 pages long, rounding out with an appendix of vernacular names of snakes and a short list of references. Many species have been illustrated for the first time. The photographs were provided by a large number of local and foreign biologists; their quality ranges from average (understandable, given that it is notoriously difficult to take a good photograph of uncooperative, fast-moving, dark-colored snakes) to startling (e.g., *Ahaetulla prasina* swallowing a lizard, p. 117). Bornean rarities illustrated range from the bizarre *Xenodermus javanicus* (p. 82) to the beautiful *Amphiesma flavifrons* (p. 169). There are a couple of misidentifications: the photograph of *Enhydris plumbea* on p. 93 is actually that of a *Xenopeltis unicolor* and those identified as *Zaocys fuscus* (p. 167) are actually *Z. carinatus*.

Other errors of omission and inconsistencies are enumerated here by topic, with the hope that these are removed if any subsequent editions are produced.

Partial or incomplete information.— For some species, detailed extralimital distributional information is provided; for others, only a brief mention that it is found in Southeast Asia or elsewhere. For example, the western part of the distribution of *Dendrelaphis pictus* includes Nepal, India, Bangladesh, and Myanmar, besides other countries mentioned. Other species that have ranges significantly larger than indicated include *Laticauda colubrina* and *Homalopsis buccata*. Patronyms are detailed in some instances, short in others. *Oligodon annulifer,* said to be known only from the unique holotype from Sabah, was re-collected in Batu Apoi, Brunei Darussalam (Das 1995). Also known from Brunei are *Ophisthotropis typica* and *Hydrablabes periops,* both of which are represented by museum specimens. The only other Sunda record of *Kolpophis annandalei* was thought to be from Sumatra, rather than Java (Das 1993). Given the confusion between *Trimeresurus borneensis* and *T. puniceus*, a sentence could be added here on the similarities between the two, and that the old Bornean reports of *T. puniceus* in fact refer to *T. borneensis*. There is published information on the diet of *Cylindrophis ruffus* in the wild, contrary to Stuebing and Inger, that indicates that it is a specialized snake-eater (see for instance, Shelford 1916:78; Smith 1943:97; Greene1997:161).

Problems with nomenclature and taxonomy.—Some taxonomic and distributional details of individual species are not made clear. Perhaps the most surprising of these is the allocation of *Xenelaphis hexagonotus* in the Xenodermatinae, rather than Colubrinae (p. 80). In the section on *Lycodon aulicus*, the species referred to and illustrated is *L. capucinus*, which earlier workers (e.g., Smith 1943) had considered a subspecies of *L. aulicus*. Taylor and Elbel (1958) and subsequent workers have treated it as a distinct species, and the Borneo record helps fill in the gap in its distribution. *Ophisaurus buettikoferi* is rendered as *Ophisaurus büttikoferi* (p. 3). Other inconsistencies include the allocation of *wagleri* (correctly) to *Tropidolaemus* (p. 14, 233, 235) and (incorrectly) to *Trimeresurus* (p. 28). A couple of species allocated to *Pareas* in this work (*laevis* and *malaccanus*) have been allocated to *Internatus* by Rao and Yang (1992), a usage followed by David and Vogel (1996). *Gongylosoma* Fitzinger, 1843 was revived from synonymy by Leviton (1964) for several Asian species previously referred to *Liopeltis*, including (in the present work) *G. baliodeirum* and *G. longicauda*.

Problems with type localities.—Page 91 gives the type locality of *Cerberus rynchops* as "?Ganjam?" Schneider's 1799 description of the species, based on watercolors in Russell (1796) was indeed from Ganjam (in Orissa State, southeastern India). The type locality of *Ophiophagus hannah* (Cantor 1836), given as unknown (p. 199), was, according to the original description, from "Sunderbuns" (= Sunderbans, at present a part of West Bengal State of eastern India and Bangladesh) and "jungle not far from Calcutta" (at present, Kolkata, West Bengal State, eastern India). The type locality of *Bungarus fasciatus*, which the authors mention as being Bengal, is, in fact, given in Russell (1796) as "Mansoor Cottah, Bengal" (at present a seaport ca. 24 km south of Ganjam, Orissa State, Southeast India), and not in the modern Indian state of Bengal.

Derivation of scientific names.—Derivations of some snake names are given as unknown or have erroneous etymology. For *Ramphotyphlops braminus*, the species name is the Latinized form of the word Brahmin (a caste among Hindus), perhaps in allusion to its brown coloration (the authors guess that the word is derived from Hindi). The derivation of the name *Chrysopelea paradisi* H. Boie in: F. Boie, 1827, can be either from the Latin ('paradisus') or the Greek ('paradeisos'), meaning an enclosed park ; it is probable therefore that the holotype was found in a park (and has nothing to do with paradise, as given in the work); the derivation of the genus *Bungarus* (as in *Bungarus fasciatus*) is from the Telugu vernacular, in which *Bungarum pambah/pamu* means 'golden snake,' and is not "New Latin" (as stated on p. 189). The species name of *Ophiophagus hannah* is derived from the name of tree-dwelling nymphs of Greek mythology, and refers to the arboreal habits of the snakes. In fact, Cantor (1838) provided a description of the habits of the species in the Sunderbans.

Omission.—Two snake species have not been listed in the checklist for Borneo: Vogel (1995) recorded *Dendrelaphis striatus* (Cohn 1905) from Kutei, Kalimantan, Borneo, and Vogel and Köhler (1996) recorded *Elapoidis fusca* Boie in Boie, 1827, from "northern Borneo." A questionable record for Borneo—*Ptyas korros*, is included, but *Oligodon semicinctus* (Peters 1862; see Wallach and Bauer 1996) is not. In the literature cited section, important works that have been missed include De Rooij (1917) and David and Vogel (1996). Details of pagination are given for some, not all, works. Incidentally, the book by Manthey and Grossmann (1997) was published in Münster, not Berlin (p. 241).

Other inconsistencies include the repetition of a paragraph in the account dealing with *Pelamis platurus* (pp. 219–220), and the use of British English in some cases and American English in others.

Despite these criticisms, this will be an invaluable reference for those working on the Southeast Asian snake fauna. The photographs will probably be more informative than the short textual descriptions, and a wise selection of photographs from 17 individual photographers contribute towards making this an attractive volume. Arguably, books like this do more for creating an interest in herpetology in the tropics than countless research papers.

PUBLICATIONS RECEIVED

La Fauna de Serpientes del Chaco Sudamericano: Diversidad, Distribucion Geografica y Estado de Conservacion, by Gerardo C. Leynaud and Enrique H. Bucher. 1999. Academia Nacional de Ciencias, Cordoba, Miscelanea N° 98. 46 pp.

This monograph reviews the 63 taxa of snakes known to inhabit the Chaco of Argentina, Bolivia, and Paraguay. Each species account includes brief summaries of common names, distribution, key characterisitcs, and natural history and is associated with a point locality map. Additional species possibly occurring in the region are also listed and the biogeographic patterns and conservation status of the Chacoan snake fauna are assessed. The main Spanish text is accompanied by a short English abstract, a bibliography of more than 125 entries, and a full page color plate of *Philodryas baroni*, one of nine snakes strictly endemic to the Chaco.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986–1999, *et. seq*. Privately published by and available from the author (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024, USA). Individual accounts available separately. Cost: US $0.10/page + postage and handling.

The most recent installments (numbers 21–23) in this series are three closely related species of *Eumeces* occurring in Texas: *E. anthracinus* (Coal Skink), *E. septentrionalis* (Northern Prairie Skink), and *E. multivirgatus* (Many-lined Skink). These new accounts comprise 29 pages in addition to a detailed range map. Axtell provides an in-depth discussion of distribution for each species in Texas, along with current taxonomy, geographic variation, conservation status, and suggestions for future work. Based on distributional grounds, Axtell suggests that instead of three distinct species, this group may comprise a single, poltypic species (*E. anthracinus*, the oldest name) showing east–west clinal variation.

Studies of the Desert Tortoise, *Gopherus agassizii*, by Angus M. Woodbury and Ross Hardy. 2000 [reprint of 1948 original]. Bibliomania!, P.O. Box 58355, Salt Lake City, Utah 84158-0355, USA. 60 pp. Softcover. US$ 12.95 (plus shipping).

Woodbury and Hardy published their monograph of the desert tortoise (including morphological aspects, as well as a diversity of ecological and life history topics) in *Ecological Monographs* in 1948. This reprint edition has been issued in celebration of the 25th anniversary of the Desert Tortoise Council. The paper was based on observations conducted in southwestern Utah over a span of more than a decade and it remains a valuable compendium of biological information on this now well-studied species.

ERRATA

A recent article by Esqueda and La Marca (1999. New reptilian species records from the Cordillera de Mérida, Andes of Venezuela. Herpetol. Rev. 30:238–240) should have contained the following statement concerning the significance of the record for *Chironius carinatus*: "First documented record for this species in the Venezuelan Andes (Lancini 1979; Lancini and Kornacker 1989), although a general distribution map in Roze (1966) suggested its presence in this mountain range." The current e-mail address of the second author is lamarca57@cantv.net.

After reviewing the list of new Georgia county records recently published (Jensen and Moulis 1999), we discovered several errors we wish to rectify.

The *Eurycea cirrigera* record listed as Decatur County should read Dooly County. Additionally, because of problems associated with the search string applied to the database, the following records were erroneously reported as new:

Eurycea guttolineata – Spalding County, previously reported in Lacy (1997).

Plethdon glutinosus – Jasper County, previously reported in Lacy (1997).

P. serratus – Clayton County, previously reported in Smith (1999).

Bufo terrestris – Lee County, previously reported in Williamson and Moulis (1994).

Hyla avivoca – Lee County, previously reported in Camp et al. (1988).

H. cinerea – Bibb County, previously reported in Jensen and Moulis (1997).

Chelydra serpentina – Cobb County, previously reported in Jensen and Moulis (1997).

Kinosternon baurii – Dooly County, previously reported in Camp et al. (1988).

Sternotherus minor – Pike County, previously reported in Williamson and Moulis (1994).

Anolis carolinensis – Clayton County and Walton County, previously reported in Jensen and Moulis (1997).

Scincella lateralis – Jones County, previously reported in Williamson and Moulis (1994).

Elaphe obsoleta – Webster County, previously reported in Williamson and Moulis (1994).

Nerodia taxispilota – Baldwin County, previously reported in Lacy (1997).

Opheodrys aestivus – Fayette County, previously reported in Lacy (1997).

FOSSIL SNAKES OF NORTH AMERICA

Origin, Evolution, Distribution, Paleoecology

J. Alan Holman

The book includes detailed accounts of the morphology and distribution of the fossil snakes of North America and remarks on their evolutionary, zoogeographic, and paleoecological patterns. The heart of the book consists of systematic descriptions of the known fossil snakes of North America and the localities where they occur. Extinct fossil taxa are discussed and illustrated, and many are re-described on the basis of new information. The book contains illustrations of diagnostic vertebrae and criteria for the identification of presently living fossil snake taxa as well as the modern characteristics and ranges of these species. It is meant to be the definitive work and standard reference for the subject, and includes a color portfolio of living snake species.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700		$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 700	$270

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2000 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@slu.edu.

Future Annual Meetings

2000 — Universidad Autónoma de Baja California Sur, La Paz, BCS, México, 14–21 June 2000 (Carlos Villavicencio, Chair).
2001 — Indiana University/Purdue University, Indianapolis, Indiana, USA, 26–30 July 2001

About Our Cover: *Eleutherodactylus cochranae*

Eleutherodactylus cochranae is a small frog endemic to Puerto Rico and adjacent islands on the Puerto Rico bank (Schwartz and Henderson. 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville, Florida). Adult males typically range from 17 to 20 mm in snout–vent length, while females are slightly larger. The frogs are locally abundant in forested habitats, where their high-pitched (dominant frequency around 3800–4000 Hz), whistle-like advertisement calls can easily be mistaken for sounds of insects. Like many *Eleutherodactylus*, these frogs are secretive, and their reproductive behavior has seldom been observed. Our cover apparently is the first published photograph of the courtship of *E. cochranae* in nature and possibly of courtship of *Eleutherodactylus* species in general.

Frogs of the genus *Eleutherodactylus* are distributed widely in Central America, northern South America, and the islands of the West Indies, where their loud advertisement calls often dominate the night sounds. With over 500 species, *Eleutherodactylus* is among the largest vertebrate genera in the world. As far as is known, all species undergo direct development in non-aquatic sites, and terrestrial reproduction probably has contributed to their success (Lynch 1971. Misc. Publ. Univ. Kansas Mus. Nat. Hist. 53:1–238); Hedges 1989. pp. 305–370 *In* Woods [ed.], Biogeography of the West Indies. Past, Present and Future. Sandhill Crane Press, Gainesville, Florida). At least one species, *E. jasperi* from Puerto Rico, is live-bearing (Drewry and Jones 1976. J. Herpetol. 10:161–165); unfortunately, this species has not been seen since 1981 and may now be extinct (Joglar and Burrowes 1996. pp. 371–380 *In* Powell and Henderson [eds.], Contributions to West Indian Herpetology: A Tribute to Albert Schwartz, SSAR. Ithaca, New York). Internal fertilization also occurs in *E. coqui* and possibly in other oviparous species (Townsend et al. 1981. Science 212:469–471). Depending on species the frogs exhibit various modes of parental behavior, including male-, female-, or biparental care of eggs and developing young (Townsend 1996. pp. 229–239 *In* Powell and Henderson, *op. cit.*). Reproductive behavior, including courtship, nest-site selection, and parental care, is undocumented for most species.

The cover photograph is a compilation of three images taken by **Kristiina Ovaska** on a wet October night in 1998 on Sage Mountain, Tortola, British Virgin Islands. A combination of serendipity and persistence allowed her to locate and photograph this courting pair entering a nest site inside a rolled-up leaf at a height of approximately 150 cm above the ground. Upon inspection of the leaf-roll two days later, a male frog attending a clutch of six eggs squirted a stream of urine at the face of the human intruder! Kristiina used a Nikon 601 camera body, AF Micro-Nikkor 60 mm f/2.8 D macro lens, and Nikon SB-23 flash to record the images on Fuji Sensia film. Dim light from a headlamp provided illumination for focusing. The three photographs were taken seconds apart as the male led the female to the nest site. Because of the short focal length of the lens, Kristiina had to be very close to the frogs—within about 25 cm—to capture these images. Although females typically are easily disturbed, these frogs in late courtship appeared impervious to her presence.

Over the past decade Kristiina has studied the courtship and reproductive behavior of *Eleutherodactylus* species and photographed these frogs in the West Indies and Panama. In addition to small, brown frogs, her photographic subjects include salamanders, snakes, and slugs. Presently she is a consultant with and principal of Biolinx Environmental Research Ltd., Victoria, British Columbia, and a research associate in the Forest Sciences Department, University of British Columbia. She lives on Vancouver Island, British Columbia.

Separation and imaging of Kristiina's photographs is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

SSAR Grants-in-Herpetology Committee Annual Report (2000)

An award in the amount of US $500 was made to each of the following individuals:

Field Research.—**John H. Malone**, University of Oklahoma. Project title: "Parental care in the Barking Frog, *Eleutherodactylus augusti*."

International.—**Antonio Freire L.**, Instituto Nacional de Higiene y Medicina Tropical "Leopoldo Izquieta Perez," Guayaquil, Ecuador. Project title: "Snake diversity of Zamora-Chinchipe Province, Southeastern Ecuador."

Conservation.—**Mike Westphal**, Oregon State University. Project title: "Long term monitoring of a diverse snake assemblage in a region facing urban expansion."

Bibliographic Research.—**Bryce A. Maxell**, University of Montana. Project title: "Herpetology in Montana, a history and an indexed bibliography of all published and gray literature."

Herpetological Education.—**Peter Uetz**, University of Washington. Project title: "A World-Wide-Web based reptile database."

Laboratory Research.—**Sarah Bouchard**, University of Florida. Project title: "Diet selection in the Slider Turtle, *Trachemys scripta*: ontogenetic shifts and associative effects between animal and plant diet items."

Travel.—**Ulrich Kuch**, University of Frankfurt. Project title: "Population systematics and biogeography of the southeast Asian temple vipers, genus *Tropidolaemus* Wagler, 1830."

2000 Grants-in-Herpetology Committee.—Anne Maglia, Richard King, Christopher Beachy, Christopher Sheil, Joseph Slowinski,

Ronald Gutberlet, Dawn Wilson, Peter Ducey, and Joseph Mendelson III (chair).

SSAR congratulates the 2000 GIH recipients and thanks the committee members for their efforts.

NEWSNOTES

Gopher Tortoise Council Awards

The Gopher Tortoise Council annually presents the J. Larry Landers Student Research Award to the best student research project concerning the biology of the gopher tortoise, *Gopherus polyphemus*, or any other relevant aspect of upland habitat conservation. Recent awards have been given for studies on gopher frogs, southern hognose snakes, and red cockaded woodpeckers, as well as those related to the gopher tortoise and its habitat. To be considered for the award, a detailed study proposal, budget, and curriculum vitae should be submitted to: *Bob Herrington, Chair, Research Advisory Committee, Department of Biology, Georgia Southwestern State University, Americus, Georgia 31709, USA (e-mail: bherring@canes.gsw.edu).* Deadline for receipt of proposals to be considered for the 2000 award is 15 August 2000.

Herpetological Collections at the University of Colorado Museum

The University of Colorado Museum encourages use of its herpetological collections. The collections include over 60,000 specimens, with particularly strong representation of the southwestern U.S. (Colorado, New Mexico, Arizona, and Utah: approximately 23,400 specimens) and Mexico (19,100 specimens). The collection of *Cnemidophorus* is one of the largest in the world, including 43 species and 11,500 specimens. Other taxa that are well-represented include *Sceloporus* (64 species and 8800 specimens), *Thamnophis* (21 species and 2300 specimens), and *Bufo* (44 species and 3800 specimens). The collections database is fully computerized, thus requests for specimen information can be answered quickly. In addition, the numbers of specimens of each species are available online at the California Academy of Science's Combined Index to Herpetology Collections website (http://research.calacademy.org/herpetology/Comb_Herp_Index.html). The collections will be moved to a renovated facility in summer, 2001, thus loan requests should be made by early 2001 or starting again in 2002. Loan or other requests can be submitted by regular mail or e-mail to Alan de Queiroz, Curator of Vertebrates, University Museum, Campus Box 218, University of Colorado, Boulder, Colorado 80309-0218, USA; e-mail: dequeiro@stripe.colorado.edu, or to Rosanne Humphrey, Collections Manager, address as above, e-mail: Rosanne.Humphrey@colorado.edu. Researchers and students are also encouraged to visit the collections. Additional information can be found at http://www.colorado.edu/CUMUSEUM/research/zoology/zoology.html.

A Working Guide to the Literature on Box Turtles (*Terrapene*)

An on-line bibliography covering life history, evolution, fossil record, external morphology, and conservation of the North American box turtles (*Terrapene*) has been compiled by C. Kenneth Dodd, Jr. The bibliography is available at:

http://www.fcsc.usgs.gov/Amphibians_and_Reptiles/Amphibians_and_Reptiles_Resear/box_turtle_bib1/box_turtle_bib1.html

MEETINGS

Societas Europaea Herpetologica 11th General Meeting

The Organizers, DPPVN/DAPTF Slovenia, the Society Radoziv and Faculty of Education, University of Maribor, are pleased to invite you to the 11th Ordinary General Meeting of Societas Europaea Herpetologica to be held in Slovenia, 16–20 July 2001. The meeting will be held in the Hall of Culture at Zalec, near Celje, with accommodations in the Hotel Zalec and elsewhere.

Details from: DPPVN/DAPTF Slovenia, Ptujska c. 91, SI-2327 Race, Slovenia; fax: +386 (0)2 788 30 51; e-mail: milan.vogrin@guest.arnes.si.

International Roundtable to Develop A Protocol on Chelonian Relocation and Heritage Collections

This working meeting will be held 26–28 September 2000 in Orlando, Florida. Special workshops and field trips are planned for 25 and 29 September. This meeting will bring together freshwater turtle and tortoise experts, veterinary and chelonian researchers, managers, educators, breeders, students, regulatory and conservation agencies, and enthusiasts from around the world and will result in a published Protocol addressing seven important areas: ethics, disease issues, genetic and systematic issues, environmental issues, socioeconomic considerations, intra-specific impacts, and heritage collection.

For registration information contact Ray Ashton or Ghislaine Guyot, Ashton Biodiversity Research & Preservation Institute, 5745 SW 75th Street #331, Gainesville, Florida 32608, USA; e-mail: Tortfarm2@aol.com. Tel. (352) 495-7449; fax (352) 495-7433.

Snake Ecology Group: Meeting 2000

The Snake Ecology Group will meet 22–24 September 2000 at the Ozark Natural Science Center, in northwestern Arkansas, USA. Workshops include "Physiological and Evolutionary Ecology," "Habitat Modeling and Habitat Utilization," "Molecular Techniques in Population Structure," and "Behavioral Ecology." Key-

note address by Dr. Stevan Arnold, of Oregon State University. Paper and poster sessions are planned. Field trips will take place following the meeting. For additional information, contact: Steven J. Beaupre, Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA; e-mail: sbeaupre@comp.uark.edu; tel. 501-575-7561.

Third Annual International Virtual Conference in Veterinary Medicine

The Third Annual International Virtual Conference in Veterinary Medicine (IVCVM) will be hosted by the University of Georgia College of Veterinary Medicine. The conference theme will be "Diseases of Reptiles and Amphibians." A "virtual conference" is the same format as a regular conference, except that it is conducted by computer over the World Wide Web. There will be no registration fees or travel expenses!

Manuscripts are acceptable as case reports or larger studies of naturally occurring or experimental disease. Diagnostic techniques also are encouraged. Any veterinary, nutritional, husbandry, research, biological data, and review papers of selected diseases also will be considered for presentation. Conference manuscripts will be presented on the World Wide Web for two years and subsequently will be archived for future reference.

The manuscript submission deadline is 1 September 2000. The proposed conference dates will be 30 September–30 October 2000. During the conference, registered participants will be able to correspond electronically with manuscript presenters and other registrants. Questions and answers concerning manuscript presentations will be posted on a bulletin board for further viewing. A "Virtual Coffee Break" is included and participants are encouraged to partake and enjoy!

Sample manuscripts and instructions to authors may be viewed at the IVCVM website: http://www.vet.uga.edu/ivcvm/.

Meetings Calendar

22–24 September 2000—Snake Ecology Group, Ozark Natural Science Center, Arkansas, USA. *Refer to meeting announcement above for details.*

26–28 September 2000—International Roundtable to Develop A Protocol on Chelonian Relocation and Heritage Collections, Orlando, Florida, USA. *Refer to meeting announcement above for details.*

16–20 July 2001—Societas Europaea Herpetologica 11th General Meeting, Slovenia. *Refer to meeting announcement above for details.*

LEGISLATION & CONSERVATION

Call for information on the status of amphibians and reptiles. This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles. We are in need of information at local, state, national, and international levels. Please direct all communications to the section editor, Travis Ryan (postal and e-mail addresses on inside front cover).

USA: Department of the Interior: The US Fish and Wildlife Service re-opened the comment period on a proposed ruling that would list populations of the mountain yellow-legged frog (*Rana mucosa*) as an endangered species in southern California under the Endangered Species Act of 1973. The mountain yellow-legged frog is distributed primarily in the Sierra Nevada Mountains of California with additional populations found in the San Gabriel, San Bernardino, and San Jacinto Mountains of southern California. Because they are separated by the Tehachapi Mountains and lie approximately 140 miles from the Sierra Nevada populations, the southern California populations are considered by the Fish and Wildlife Service to comprise Distinct Population Segments (DPS); this designation makes the southern California DPS eligible for federal protection as an endangered species. A limited, unpublished allozyme analysis suggests that the two groups are indeed distinct, although further studies are warranted to determine the degree of genetic divergence.

Rana mucosa in southern California are generally found at lower elevations (760–1820 m) than those in the Sierra Nevada Mountains (usually < 1800 m). Most adults in the southern California DPS are associated with shaded stream systems; larvae develop in the streams and require 1–2.5 yrs to reach metamorphosis. Populations were abundant in the DPS prior to the 1960's; presently *R. mucosa* is believed to be absent from more than 99% of its historical range. The leading causes of declines are likely habitat destruction (e.g., logging, water development, irrigation, etc.) and the introduction of non-native predators/competitors. The comment period on this proposal ended 19 April 2000.

For further information contact: Field Supervisor, U.S. Fish and Wildlife Service, Carlsbad Fish and Wildlife Office, 2730 Loker Avenue West, Carlsbad California 93003, USA.

USA: Department of the Interior: The US Fish and Wildlife Service proposed to designate over 400,000 acres of land in Contra Costa, Alameda, San Joaquin, and Santa Clara counties in California as critical habitat for the Alameda whipsnake, *Masticophis lateralis euryxanthus*. The Alameda whipsnake has been under federal protection since 5 December 1997 when it was listed as a threatened species under the Endangered Species Act of 1973. Adoption of critical habitat proposal would prohibit destruction or adverse modification of whipsnake habitat by activities funded, authorized, or carried out by the federal government. Critical habitat is that considered essential for the conservation of the species and may require special management and/or protection. In the case of *M. lateralis euryxanthus*, the critical habitat is chaparral, although individuals may occasionally use conjoining grassland, oak savanna, and (less frequently) oak-bay woodland. Males maintain overlapping home ranges that average about 14 acres. No less than five populations of *M. lateralis euryxanthus* have been documented, and the area covered by the proposal would protect critical habitat for all five populations. The comment period on this proposal ended 8 May 2000.

For further information contact: Field Supervisor, U.S. Fish and Wildlife Service, Sacramento Fish and Wildlife Office, 2800 Cottage Way, Suite W – 2605, Sacramento, California 95825, USA.

USA: Department of the Interior: On 19 January 2000 the U.S. Fish and Wildlife Service, acting under the emergency rule of the Endangered Species Act of 1973, declared populations of the California tiger salamander (*Ambystoma californiense*) in Santa Barbara County as endangered. This emergency ruling is effective for 240 days, expiring on 15 September 2000. In justifying the ruling, the FWS noted that of the 14 known breeding sites for *A. californiense* in Santa Barbara County, more than half had been destroyed in the preceding year and a half, placing the population in peril of extinction. All of the breeding sites are located on privately owned land, much of which is scheduled for conversion to agricultural land. The Santa Barbara County populations are collectively regarded as a Distinct Population Segment (DPS); the FWS is permitted to treat DPSs as equivalent to species under the Act. Within the range of *A. californiense* there are at least seven genetically distinct populations and the Santa Barbara County DPS is effectively isolated from the other six populations by the coastal mountain ranges. More than 40 air miles separate the Santa Barbara County DPS from the closest population with which it shares recent ancestry. The isolated nature of the Santa Barbara County DPS eliminates the likelihood of recolonization in the event of a local extinction, which would therefore result in the loss of both geographic range and genetic diversity for the species.

Like most other *Ambystoma*, *A. californiense* breeds in vernal ponds or seasonal pools. The larval period is relatively short, with only 10 weeks or so required for larval development. Recently metamorphosed juveniles and adults travel considerable distances from the larval habitat, and spend the majority of the year in upland habitats (primarily grasslands, oak woodlands, and coastal scrub forests) that surround breeding sites. In addition to habitat alteration, loss, and fragmentation, introduced species such as bullfrogs and mosquitofish are potential factors that have led to the imperiled state of the Santa Barbara County population.

In addition to the temporary emergency action, the FWS has also proposed to list the Santa Barbara County DPS as an endangered species under the normal procedures of the Act. The comment period on this proposal ended 20 March 2000.

For further information, contact: Grace McLaughlin, U.S. Fish and Wildlife Service, Ventura Fish and Wildlife Office, 2493 Portold Road, Suite B, Ventura, California 93003, USA.

International: Convention on International Trade in Endangered Species: In last issue's Legislation and Conservation column (Herpetol. Rev. 31:5–6), a proposal submitted by the U.S. Fish and Wildlife Service to C.I.T.E.S. requesting an Appendix II listing for the spotted turtle (*Clemmys guttata*) was highlighted. This proposal was heard at the 11th meeting of the Conference of the Parties, held in Kenya 10–20 April 2000. The proposals listed below were also reviewed by the Animals Committee at the Conference. The fate of these proposals will be covered in upcoming Legislation and Conservation columns.

Reptiles: Testudinata: Emydidae: Inclusion in Appendix II: *Cuora amboinensis*, *C. aurocapitata*, *C. flavomarginata*, *C. galbinifrons*, *C. maccordi*, *C. pani*, *C. trifasciata*, *C. yunnanensis*, and *C. zhoui*.

Reptiles: Testudinata: Testudinidae: Transfer from Appendix II to Appendix I: *Geochelone sulcata*, *Malacochersus tornieri*.

Reptiles: Testudinata: Cheloniidae: Transfer from Appendix I to Appendix II (with restrictions): *Eretmochelus imbricata*.

Reptiles: Crocodylia: Transfer from Appendix I to Appendix II: *Crocodylus moreletii* (Sian Ka'an and Quintana Roo populations only).

Reptiles: Squamata: Sauria: Transfer from Appendix I to Appendix II: *Varanus melinus*.

Reptiles: Squamata: Serpentes: Inclusion in Appendix II: *Crotalus horridus*.

Amphibia: Anura: Bufonidae: Deletion from Appendix II: *Bufo retiformis*.

Amphibia: Anura: Ranidae: Inclusion in Appendix II: *Mantella* spp.

For a brief description of Appendix I and Appendix II, see Herpetol. Rev. 31:5–6; for a more thorough definition visit http://www.cites.org/CITES/eng/index.shtml.

CAMBODIA: Phnom Penh: The Workshop on Trade in Tortoises and Freshwater Turtles in Asia. This workshop, held 1–4 December 1999 and organized by the Wildlife Conservation Society, World Wildlife Foundation, and TRAFFIC, was convened to address the state of chelonian conservation throughout Asia. The number of Asian turtle species regarded as threatened and endangered is growing rapidly; the Asian Turtle Trade Working Group addressed short- and long-term strategies for stemming the loss of species. The Working Group identified two primary areas of turtle trade that threaten the status of Asian species: consumption trade and pet trade. Consumption trade includes both collection of wild turtles and turtle farming for subsistence, as well as the turtle shell by-product industry. The Asian pet trade is centered on exotic species such as *Geochelone elegans* (Indian star-nosed turtle) and Australian turtles in the genera *Chelodina* and *Carettochelys*. The Working Group concluded that the available trade data underestimate the annual take for virtually all species. Under-reporting hinders the generation of reliable data on the effects of trade on population and species status; however, an evaluation of the available data led to the conclusion that for 84 species under consideration, 63 species (75%) should be placed in one of the IUCN threatened categories (Extinct, Critically Imperiled, Endangered, or Vulnerable), and trade was a considerable factor for 52 species (62%).

The Working Group identified a number of conservation priorities and recommendations, including:

- enforcement of all existing local, state, and national legislation;
- improvement of existing legislation for turtle conservation throughout the region;
- development of adequate mechanisms to handle confiscated turtles;
- listing all 93 species of the Indomalayan, Autralasian, and eastern Palearctic biogeographic regions in CITES Appendix II (save for those species listed in [or appropriate for] Appendix I);
- consideration of listing all chelonian species worldwide in CITES Appendix II;
- monitoring field and market data to improve understanding of the market impact on natural turtle populations;
- supporting management programs that have as a primary goal the preservation of genetic diversity within natural populations; and
- establishment of outreach programs to educate the peoples in the Indo-australasian region (and the rest of the world) regard-

ing the consequences of the turtles trade and the loss of chelonian biodiversity.

The Workshop was funded by WCS, WWF, and TRAFFIC, with support from the German Federal Agency for Nature Conservation, Ministry of Environment, Nature Conservation and Nuclear Safety; the Office of Scientific Authority, U.S. Fish and Wildlife Service; the Chelonian Research Foundation, USA; Kari and Andrew Sabin; and the Kadoorie Farm & Botanic Garden, Hong Kong.

CURRENT RESEARCH

Please refer to Vol. 31, Number 1 for information concerning submissions to this section. Section editor contact information is located on the inside front cover of this issue.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.herplit.com/contents

Defensive Strike of the Eastern Brownsnake

Eastern Brownsnakes are the most significant contributor to human snakebite fatalities in Australia. A previous study by the authors examined free-ranging, radio-tagged *Pseudonaja textilis* through repeated, intentional encounters, to document the ways that body size and temperature influence the probability of encountering this species, as well as the way that this species responds to these encounters. In this study, the authors investigated factors that led to a defensive strike, as well as the speed and accuracy of that strike, in captive brownsnakes. Responses to human harassment (neck displays, time taken to strike, strike accuracy and speed, and effectiveness of bite) were documented with high speed film. Results indicate that captive brownsnakes were tolerant to harassment at temperatures similar to those in the field, and that smaller snakes were more likely to attempt escape than were larger snakes. Body temperature was found to have little effect on many of the variables measured (frequency of display and bluff, duration of strike, strike distance, mean overall strike speed, mean fastest strike speed, and accuracy of strike). Results indicate that type of prestrike display (full neck display or minimal display) was related to strike speed and accuracy. Finally, the data indicate that captive *Pseudonaja textilis* is reluctant to deliver firm bites when continuously harassed by humans, and it is reported that only about 15% of recorded strikes had the potential to cause significant envenomation.

WHITAKER, P. B., K. ELLIS, AND R. SHINE. 2000. The defensive strike of the Eastern Brownsnake, *Pseudonaja textilis* (Elapidae). Functional Ecology 14:25–31.

Effects of Age and Size on Performance and Metabolic Rates in Metamorph Southern Toads

During metamorphosis, individuals undergo significant changes in physiology, morphology, and behavior; body size and timing of metamorphosis are thought to have significant effects on fitness. Beck and Congdon studied the effects of individual variation in age and size at metamorphosis on performance and metabolic rates of *Bufo terrestris*. Variation in age and size at metamorphosis were experimentally induced by rearing ten clutches of eggs to metamorphosis under different food levels and temperature regimes. Sprint speed and endurance were measured as indicators of performance, whereas metabolic rate was measured indirectly with a closed circuit respirometer. Metabolic rate, sprint speed, and endurance of metamorphs were found to be negatively related to age at metamorphosis and positively related to mass at metamorphosis. The authors state that decreases in larval period duration and increases in mass at metamorphosis may be advantageous in terms of locomotor performance, but disadvantageous because of costs of increased energy expenditure on maintenance. Locomotor performance was not significantly affected by either of the treatments or their interaction, after effects of age and size at metamorphosis were removed. Finally, metamorph physiology, and possibly fitness, may be affected by aspects of the larval environment by mechanisms other than differences in age and size at metamorphosis.

BECK, C. W., AND J. D. CONGDON. 2000. Effects of age and size at metamorphosis on performance and metabolic rates of Southern Toad, *Bufo terrestris*, metamorphs. Functional Ecology 14:32–38.

Wetland Size, Hydroperiod, Amphibian Species Richness, and Implications for Wetland Regulation

Using data on wetland size, relative hydroperiod, and relative species richness of amphibians in depression wetlands of the southeastern United States, the authors tested three assumptions: (1) small wetlands contain water for short periods of time; (2) smaller wetlands support fewer species than larger wetlands; and (3) species found in smaller wetlands can also be found in larger wetlands. The amount of time that a wetland holds water during an annual hydrological cycle was used as a drying score of relative measures of annual hydroperiod at the Savanah River Site, South Carolina. Eighty-six sites were visited fifteen times between January 1996 and December 1998. Wetland sizes were obtained from the literature. Adult and larval amphibian diversity was sampled with dip nets and traps at 22 wetlands. Results indicate a significant but weak relationship between wetland size and hydroperiod, but no relationship between amphibian species richness and wetland size. Amphibian species richness was found to be related to the hydroperiod of a wetland. Though the presence of most amphibian species was found to be random with respect to wetland size, results indicate that a pattern of species turnover exists along

a gradient of hydroperiod. Empirical studies based on synthetic models of lentic communities support their prediction that short-hydroperiod wetlands support unique groups of species. Based on these results, the authors conclude that wetland size is not a good predictor of wetland hydroperiod or amphibian species richness at the Savanah Research Sites. Hydroperiod length should be considered as a primary criterion in establishing wetland management and regulations.

SNODGRASS, J. W., M. J. KOMOROSKI, A. L. BRYAN JR., AND J. BURGER. 2000. Relationships among isolated wetland size, hydroperiod, and amphibian species richness: implications for wetland regulations. Conservation Biology 14(2):414–419.

Rib Loss in Anurans

The absence of ribs has been considered a derived condition that is widespread among most anurans, whereas the presence of free ribs is presumed to be the plesiomorphic condition shared by only a few families of Recent anurans. Chondrification, ossification, and development of the neural arches, transverse processes, and ribs were examined in representatives of several families of frogs (Bufonidae, Discoglossidae, Hylidae, Pelobatidae, Pelodytidae, Pipidae, and Ranidae) to examine the morphological evolution of "vestigial" traits, as well as to investigate the similarity of developmental paths involved in apparent rib loss. Examination of cleared and double-stained anuran larvae and metamorphs corroborated the observation that free ribs are absent in several anuran groups; however, the authors provide evidence for the existence of larval rib rudiments in several anuran genera (*Bufo, Discoglossus, Hyla, Pelobates,* and *Rana*). The authors state that heterochrony may have played a significant role in processes underlying reduction of ribs. Finally, the authors identified a shift in the relative timing of ossification of vertebral elements among several lineages of frogs.

BLANCO, M. J., AND B. SANCHIZ. 2000. Evolutionary mechanisms of rib loss in anurans: a comparative developmental approach. Journal of Morphology 244:57–67.

Differential Effects of Calcium in the Skin of Tadpoles

Amphibian metamorphosis results in the reorganization of most tadpole tissues and organs, and is controlled by thyroid hormones. Ecological factors are known to effect developmental rate, and anuran skin is known to be sensitive to chemical signals (including ion concentrations) in the environment. The authors describe the effects of Ca^{++} (a known cellular signal expected to initiate metamorphic events) on the development of two larval organs (tail and skin) with different metamorphic fates; effects of Ca^{++} treatment on the thyroid also was examined. Treatment of tadpoles with calcium during early development induced early tail regression, shortening of the intestine, forelimb emergence, and keratinization of body epidermis. Results of this study suggest that a calcium-elicited signal leading to these effects is likely mediated by the thyroid gland.

MENON, J., E. E. GARDNER, AND S. VAIL. 2000. Developmental implications of differential effects of calcium in tail and body skin of anuran tadpoles. Journal of Morphology 244:31–43.

Functional Role of Trunk Muscles During Locomotion in Adult Amphibians

The authors review the functional roles played by amphibian epaxial and hypaxial trunk muscles during locomotion, and identify transitions in these roles that have taken place during the evolution of amphibians. The usual modes of locomotion for Caudata, Anura, and Gymnophiona are discussed, and particular attention is paid to those modes that rely heavily or exclusively on axial musculature. Despite the uncertain relationships among the Lissamphbia and morphological differences between modern lissamphibians and the earliest tetrapods, the authors propose that it is possible to reconstruct the configuration of the trunk muscles in the common ancestor of Lissamphibia. Based on evidence of fossil data and the assumption of lissamphibian monophyly, the authors conclude that the common ancestor of lissamphibia was most likely salamander-like in body form. Multiple functional and morphological elaborations of the axial musculature of amphibians are summarized, and these elaborations appear to be associated with movement in terrestrial habits, as well as with subsequent locomotor specializations in frogs and caecilians.

Effects of UV-B Radiation on Amphibian Embryos in the Southeastern United States

In order to test the sensitivity of pond-breeding amphibians in the southern Appalachian Mountains, the eggs of three species of frog (*Hyla chrysoscelis, Pseudacris triseriata,* and *Rana sylvatica*) and one salamander (*Ambystoma maculatum*) were exposed to varying levels of UV-B radiation. A randomized block design was utilized with experimental treatments consisting of: (1) blocking of 98% UV-B; (2) 80% transmission of ambient UV-B; and (3) direct exposure to solar radiation. Eggs were collected from natural breeding sites in early developmental stages. Though deformities were not common, anurans showed a weak correlation between higher deformity rates and unshielded (treatment 3) con-

trols. Between *Pseudacris* and *Hyla*, deformities were significantly lower in embryos shielded from UV-B; these species tend to oviposit small egg masses or monolayers on the water surface of sunny habitats. This may indicate an increased vulnerability to deformities induced by UV-B. There was no evidence of an increase in mortality due to increase in exposure to UV-B in any of the study species. Because of the complex nature of amphibian declines and the richness of amphibian species in the southeastern United States, the authors encourage further study of the sensitivity of these organisms to UV-B.

Mechanism and Sensitivity of Pit Organs in *Python*

An investigation was undertaken by the authors to determine the spectral sensitivity of pit organs and the mechanism utilized in infrared signal transduction. Young Burmese (*Python molurus bivitattus*) and ball (*P. regius*) pythons were chosen for electron microscopy, immunocytochemical labeling, histology, and infrared imaging of pit organs. Compared to the photoreceptors of the retina, receptors of the pit organ were found to absorb a different range of infrared wavelengths and displayed distinctly different morphology. The range of wavelengths to which the boid and crotaline snakes showed greatest absorption is the emission range of the snakes' prey items. Further investigation did not reveal the make-up of the infrared absorber in the pit organs. The pit organ shows the greatest known sensitivity to infrared wavelengths. Therefore, elucidation of the mechanisms and neural pathways involved could lead to further developments in herpetology as well as the improvement of artificial infrared detectors.

The Role of Generalized Tadpoles as Macrophagous Predators

The authors challenge the beliefs that tadpoles are limited primarily to herbivory, and that ephemeral ponds contain fewer predators. In addition, they call for further investigation into the potential role of generalized tadpoles as keystone predators in organizing pond communities. Research was conducted using the wood frog (*Rana sylvatica*) and the green frog (*R. clamitans*) in both laboratory and natural pond settings. In the laboratory experiment, tadpoles were observed attacking and consuming macroinvertebrates, including some >5 times the length of the attacking tadpole. The survival of the prey items was significantly correlated to the presence of tadpoles. Field experiments conducted in eight ephemeral ponds revealed extensive egg predation of *R. sylvatica* by larval *R. clamitans*—egg masses of two ponds (totaling over 58,000 embryos) were completely consumed by larval *R. clamitans* within two weeks. The authors observed that many ecological models have been based on the assumption that generalized tadpoles do not function as macrophagous predators, an assumption which appears to be false. Finally, the authors provide an extensive table summarizing evidence from literature on macrophagy by generalized tadpoles.

Vittorio Erspamer (1909–1999)

JOSE MIGUEL CEI
Hilario Cuadros 81, 5501 Godoy Cruz
Mendoza, Argentina

and
RODOLFO RUIBAL
Biology Department, University of California
Riverside, California 92521-0427, USA

With the demise of Professor Vittorio Erspamer, on October 26, 1999, in Rome, the world of research biology lost one of its most active and significant investigators. The unique qualities of Erspamer's pharmacological research were augmented by his exceptional ability for scientific synthesis. He extended his research into the evolutionary and taxonomic ramifications of his results, and particularly as they applied to herpetology. The major subject of his studies were the biogenic amines and polypeptides that he isolated from the cutaneous glands of amphibians.

Erspamer was born in Malosco (Trento, Italy) on July 30, 1909, when this region was still part of the Austro-Hungarian empire.

After the return of the area to Italy he attended the University of Pavia, and graduated with a doctorate in medicine in 1935. During 1935–1938 he was a research assistant in the University Institute of Comparative Anatomy and Physiology. He worked under the director, Prof. Maffo Vialli, doing histochemical and comparative research. Erspamer always considered Maffo Vialli as an outstanding teacher and the person that transmitted to him the great value of comparative research. Erspamer spent a year (1939) in Germany on a fellowship at the Universities of Berlin and Bonn. From 1940–1947 he was an Assistant Professor at the Pharmacological Institute of the University of Rome. Despite the difficulties of the war years he was able to continue his research. In 1947 he became a full Professor and Chairman of Pharmacology in the faculty of medicine at the University of Bari, Italy. He remained there until 1955 and then continued in the same role at the University of Parma (1955–1967) and finally returned to the University of Rome (1967–1984) as professor of pharmacology and the director of the Institute of Medical Pharmacology. After his retirement in 1984 he was named Emeritus Professor of the University of Rome. From that date until one week before his death he continued active research in his laboratory at the institute. His energy and enthusiasm continued and in September 1999, when he was nearly 90 years old, he was eagerly soliciting collaboration to undertake research on the bradykinins of the skin of cyclostomes. His interest was to pursue the phylogeny of the bradykinins, which are frequent in the skin glands on many amphibians.

Erspamer's early research (1937–1946) emphasized the identification of the secretions of chromaffin cells in the cutaneous glands of amphibians. During this same period he also did some interesting research on the secretions of cephalopods. During this time he gave the name "enteramine" to a substance extracted from the amphibian glands. In 1949, in the United States, Rappaport isolated an identical substance, 5-hydroxytryptamine, and named it serotonin. In 1952, Erspamer and Asero isolated 5-hydroxytryptamine from the skin of *Discoglossus pictus* and started a search for indolealkylamines in the cutaneous gland of other amphibians. More than 500 species were screened and the taxonomic distribution of the secretions was mapped. Indolealkylamines were discovered, in various combinations, not only in the Bufonidae (where it was reported to be most common by Cei, Erspamer, and Roseghini in 1972) but also in a diversity of families, genera, and species—Pipidae, Liopelmatidae, Pelobatidae, Leptodactylidae, Myobatrachidae, Ranidae, etc. Using the same techniques, Erspamer undertook a search for other biogenic amines—imidazolealkylamines, monohydroxy-phenylalkylamines, and catecholamines. It was discovered that the patterns of distribution of these amines within the Amphibia were sometimes unique. For example, catecholamines (epinephrine and related amines) are exclusively found in species of *Bufo*, which contain all of the precursor enzymes in the skin. The presence of various amines has also been useful in the diagnosis of species and in taxonomic keys.

Simultaneous to the research on the amines, Erspamer and his collaborators also studied bioactive peptides of batrachian skins. Some of these molecules were equivalent to neurotransmitters, neuromodulators, and other neuroendocrine agents present in mammalian tissues. The extensive screening led to the identification of more than one hundred bioactive peptides, structurally and pharmacologically belonging to a diversity of biochemical families such as takykinins, bradykinins, caeruleins, sauvagins, bombesins, opioids, and others. Hundreds of anuran species were obtained for study from North and South America, Europe, Africa, eastern Asia and Australia. Since 1959, collaborators such as Cei, Endean, Visser, and others have been active doing field work. Erspamer himself participated in some of the field work in Chile, eastern Asia, and South Africa.

The interest in these studies and discoveries is the fact that these batrachian peptide components are also found in mammalian tissues. In some cases the molecular equivalence between the amphibian and mammalian compounds is striking—caerulein versus choleocystokinin and gastrin; physalaemin versus substance P. More surprising is the fact that some of the batrachian peptides were discovered first and led to the identification of the mammalian analogs (bombesin, sauvagine and opioid peptides). Erspamer (1994. *In* H. Heatwole [ed.], Amphibian Biology, Volume 1, The Integument, pp. 178–350, Surrey Beatty and Sons) has provided an excellent and detailed summary of his work and that of others on the bioactive peptides (and other secretions) of amphibian skin glands. He makes clear the fact that the availability of synthetic amphibian peptides (such as bombesin) permitted and preceded the discovery of mammalian equivalents.

The work of Vittorio Erspamer and his influence on other researchers can be appreciated in this brief résumé of his investigations. His contribution to the advancement of herpetology is clearly evident. Furthermore, his humane personality transmitted an example of enthusiasm, scientific integrity, and critical ability, combined with a modest approach. Those who collaborated with him are left with a clear memory of his generous cooperation and sincere friendship. He always expressed himself with crystal clarity. The high regard in which he was held by research biologists was clearly demonstrated at meetings and in publications. He was nominated several times for the Nobel Prize, which he certainly merited, but unfortunately did not receive. We will remember him with respect and fondness.

How Far North Would the Gecko Move if the Gecko Could Move North?

AARON M. BAUER
Department of Biology, Villanova University
800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA
e-mail: aaron.bauer@villanova.edu

The Geographic Distribution section of *Herpetological Review* typically contains new locality records of a number of lizard species that have recently become established in the United States. Among the most frequently documented taxa with expanding ranges is *Hemidactylus turcicus*, the Mediterranean gecko. The first American record for this species was from Key West, Florida (Fowler 1915) and it was subsequently introduced into Texas (Conant 1955; Flower 1933). Isolated populations have since been established throughout the Gulf states and those bordering Mexico,

as well as in Oklahoma, Arkansas, and Georgia (Conant and Collins 1998; Painter et al. 1992; Paulissen and Buchanan 1990). In a recent issue of *Herpetological Review*, Eason and McMillan (2000) documented a South Carolina state record for this species (Charleston County, 32°48.300'N, 80°03.157'W), which they reported as the northernmost distribution of *H. turcicus* in the southeastern United States. Although this does appear to be the first record for the state, it is certainly not the northernmost record of the Mediterranean gecko in eastern North America. Knight (1993) had earlier reported on an established population on the campus of Virginia Polytechnic Institute and State University in Blacksburg, Virginia (approx. 37°14'N, 80°25'W; 495 km N of the South Carolina site), which he regarded as the northernmost breeding population of Mediterranean geckos in America. The true northernmost record for *H. turcicus*, however, belongs neither to South Carolina nor to Virginia, but to Maryland, where Norden and Norden (1991) documented the establishment and persistence of this species in south Baltimore (approx. 39°30'N, 76°37'W; 405 km NE of Blacksburg and 784 km NNE of Charleston County). Although no more northern localities have been identified, the survival and reproduction of this species in Baltimore suggests that urban environments in Philadelphia and perhaps even New York could also support colonies of this successful lizard.

The locality records of an introduced species are hardly worth quibbling over, but this case is instructive as it suggests that some authors of Geographic Distribution accounts in *Herpetological Review* may be missing relevant citations that appear in region- or taxon-specific publications. Although Norden and Norden (1991) was not indexed by *Zoological Record*, Knight (1993) was and would have, therefore, been fairly easy to locate. Although *Herpetological Review* has become the most frequently used outlet for the publication of notes documenting amphibian and reptile range extensions, it is not the only such outlet and authors should make every effort to comb the herpetological literature thoroughly before coming to the conclusion that they have located all publications pertinent to their own work.

A Brief History of Snakes

HUSSAM ZAHER

e-mail: rieppel@fmnh.org

With the introduction of Pythonomorpha, Cope (1869) implicitly proposed the derivation of snakes from a mosasauroid ancestor (see also Nopcsa [1923]; McDowell and Bogert [1954] linked snakes with aigialosaurs through *Lanthanotus*). Although this hypothesis is not without problems of its own (Underwood 1957; Rieppel 1988), the marine origin of snakes that this scenario implies also clashes with data derived from the sensory system (Senn and Northcutt 1973; Underwood 1970; Walls 1940), which suggest a terrestrial, indeed fossorial or burrowing, ancestry of snakes. The recent re-analysis by Caldwell and Lee (1997) of snake-like fossils with limbs first discovered by Haas (1979, 1980a, b) in marine sediments from the Lower Cenomanian (early Upper Cretaceous) of Ein Yabrud, north of Jerusalem, provided a new impetus for the discussion of snake origins. In his initial description of *Pachyrhachis*, Haas (1979) placed *Pachyrhachis* in the Varanoidea but outside Serpentes, because he realized that those characters which this fossil taxon does share with snakes are macrostomatan characters, i.e., features characteristic of relatively advanced snakes (Rieppel 1988, 1994). It therefore seemed prudent to interpret *Pachyrhachis* as a varanoid, convergent upon macrostomatans in some cranial characters (Haas 1979). In spite of these character conflicts, *Pachyrhachis* became the textbook example for an ideal intermediate between fossil varanoids (mosasauroids) and snakes (Carroll 1988). This interpretation of *Pachyrhachys* has recently been supported by a series of papers (Caldwell and Lee 1997; Lee 1997, 1998; Lee and Caldwell 1998; Scanlon et al. 1999) which we briefly review below.

In his initial analysis of snake relationships, Lee (1997) constrained the search for the sister-group of Serpentes to Varanoidea, excluding all other squamates from the data matrix by rooting the analysis with a hypothetical ancestor. This prevented a test of snake relationships with other squamates, such as the fossorial amphisbaenians and dibamids, which had previously been recognized as at least potential sister-taxa of snakes (Estes et al. 1988; Rage 1982). At a later stage, *Pachyrhachis* was added to the analysis, and found to be the most basal snake, linking this group again to mosasauroids (Caldwell and Lee 1997; Lee and Caldwell 1998). Still later, other squamates were added to the analysis to test for global relationships among the group, and the mosasauroid–*Pachyrhachis*–snake clade was again supported, in spite of the

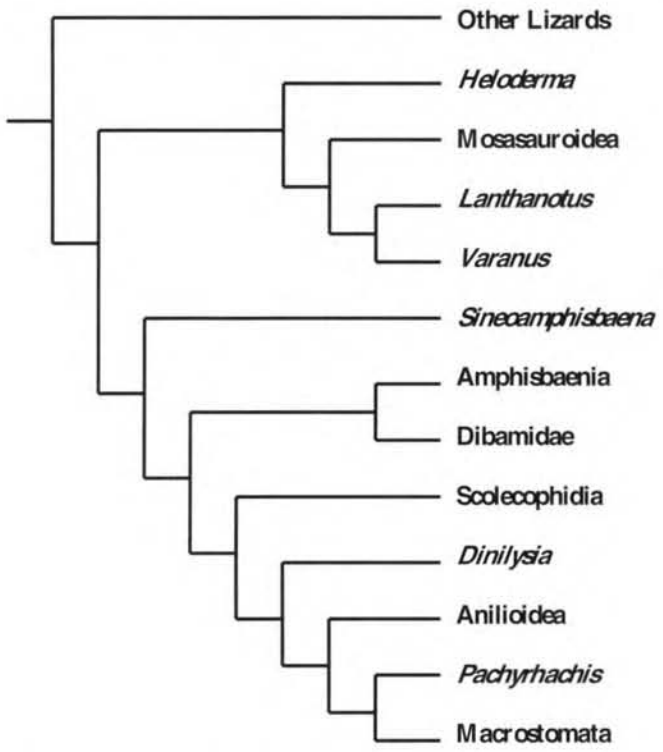

FIG. 1. Cladogram of higher-level interrelationships of snakes obtained by the reanalysis of the data of Lee (1998). This cladogram rejects Lee's hypothesis of sister-group relationships of mosasauroids and snakes as well as the basal position of *Pachyrhachis* with respect to extant snakes. See text and Rieppel and Zaher (2000b) for further discussion.

fact that *Pachyrhachis* had been found to be the sister-taxon of macrostomatans in a critical evaluation (Zaher 1998) of the data set presented by Caldwell and Lee (1997). The criticism raised by Zaher (1998) was rebutted by Lee (1998), but at the same time this latter study used all snakes other than *Pachyrhachis* as a single terminal, constraining the analysis in a way that would not allow an empirical test and potential refutation of Zaher's (1998) results.

We have conducted a detailed review and analysis of the characters offered by Lee (1998) in support of a basal position of *Pachyrhachis* among snakes, and a sister-group relationship of snakes with mosasauroids. This review was not intended to result in a well corroborated reconstruction of global squamate relationships, but instead, focused on the phylogenetic relationships of *Pachyrhachis* and its bearing on snake origins. A full scale reconstruction of squamate relationships would have to introduce additional terminals and/or split up terminals, coded at the family level by Lee (1998), in order to reduce polymorphism among terminals. Alternatively, the intrafamilial relationships of all terminals would have to be reconstructed in order to correctly infer the plesiomorphic character-states for each squamate family. This amounts to a long term project to be pursued in the future. At this time, we chose to critically assess the character definitions proposed by Lee (1998) as they relate to the anatomy of the dentition (Zaher and Rieppel 1999), of the braincase (Rieppel and Zaher 2000a), and of the lower jaw (Rieppel and Zaher 2000b). We corrected the data set of Lee (1998) where necessary, and subjected it to various manipulations in repeated searches (deletion versus retention of controversial characters, ordering versus not ordering of multistate characters, adding versus not adding characters that were not included in the original study, and rooting on the actual outgroups versus rooting on the reconstructed ancestor). In all cases, however, the terminal taxon Serpentes was broken up into Scolecophidia, *Dinilysia*, Anilioidea, and Macrostomata (for the validity of these terminal taxa see Rieppel, 1988; Kluge, 1991; Cundall et al., 1993). All searches uniformly showed *Pachyrhachis* to be the sister-taxon of Macrostomata, and the snakes did not group with mosasauroids, but always grouped with the amphisbaenian-dibamid clade (Fig. 1, Rieppel and Zaher 2000b). The implementation of Lee's (1998) tree on our corrected and amended data set (Rieppel and Zaher 2000b), using his own search procedure (i.e., retention of all characters, retention of the multistate characters as ordered, and rooting the tree on a reconstructed ancestor; Lee [1998]), results in a tree which is 15 steps longer compared to our most parsimonious solution (with a total tree length of 637 instead of 622 steps for 239 characters). Additionally, we applied the reverse successive weighting strategy developed by Trueman (1998) to our corrected data set and found that the amphisbaenian–dibamid–snake clade is retained as the most parsimonious solution after two iterations of deletion of unequivocal synapomorphies (ci = 1; given the initial data matrix of 239 characters, 76 unequivocal characters were deleted for the first iteration, and 9 characters for the second iteration). Only after three iterations of deleting unequivocal synapomorphies (another 15 characters were deleted) did we recover the varanoid–mosasauroid–snake clade, but the relative relationships among all snakes, including *Pachyrhachis*, remained unresolved. A fourth iteration recovered the amphisbaenian–dibamid–snake clade again, with *Pachyrhachis* as sister-taxon of Macrostomata in a tree devoid of any unequivocal synapomorphies. These results indicate that the data set does incorporate a weaker signal for a varanoid–snake–mosasaur relationship as compared to the signal for the amphisbaenian–dibamid–snake clade, and that both these signals are independent of the position of *Pachyrhachis*.

The reasons for the different results are manyfold: they range from changes of character delimitation to different codings to different search procedures. Of these, the character data base proved to be the most influential factor. To name but a few examples, the marginal teeth of mosasauroids are not thecodont, nor ankylosed to the rim of distinct sockets, but modified pleurodont as described and defined by Zaher and Rieppel (1999). A recumbent position of replacement teeth in mosasauroids is the result of post-mortem displacement (Edmund 1960; Polcyn et al. 1999; Zaher and Rieppel 1999). The plesiomorphic type of tooth implantation in snakes is again pleurodonty (as shown by scolecophidians), and *Pachyrhachis* shares with alethinophidian snakes a synapomorphic type of tooth attachment derived from pleurodonty (Zaher and Rieppel 1999).

The formulation of broad character definitions to accommodate distinct morphologies, typical of snakes and mosasaurs respectively, can lead to the oversimplification of complex, non-comparable, structures by lumping those within one character. For example, the character definition referring to the footplate of stapes as "tightly surrounded by flanges from prootic and opisthotic" refers to three distinct structures: the *crista prootica*, the *crista*

interfenestralis, and the *crista tuberalis* (*sensu* Oelrich 1956). The bony flanges surrounding the footplate of the stapes in non-ophidian squamates, including mosasauroids, are the *crista prootica* and *crista interfenestralis*, the plesiomorphic condition. In snakes, the footplate of the stapes together with the *fenestra rotunda* are surrounded by the *crista prootica* and the *crista tuberalis*, which together form a *crista circumfenestralis* enclosing a juxtastapedial recess. This juxtastapedial recess, recognized as an ophidian synapomorphy, is associated with the modification of the perilymphatic system which forms a re-entrant fluid circuit (Estes et al. 1970; Rieppel and Zaher 2000a; Wever 1978; Lee [1998] recognized this character delimitation as problematic, but continued to use it as a potential pythonomorph synapomorphy).

The definition of some characters fails to reflect ontogeny. For example, amphisbaenians, dibamids, and snakes share the formation of a "compound bone" which incorporates the (dermal) surangular and prearticular, and the (chondral) articular (a character wrongly polarized by Lee 1998). The absence of a "subcoronoid fenestra" (exposing the surangular between the coronoid and the prearticular on the medial surface of the lower jaw) is coded as a putative homology and accepted as a synapomorphy of mosasauroids, *Pachyrhachis*, and snakes (convergent in amphisbaenians and dibamids). However, this character is not applicable to taxa with a compound bone (snakes, amphisbaenids, and dibamids). Indeed, Bäckström (1931, fig. 17) shows the prearticular to completely conceal the surangular in the medial view of an embryonic jaw of *Natrix natrix* prior to the fusion of these elements to form a compound bone, and the same is observed in embryos of *Anilius scytale* (pers. obs., unpubl. data). For this reason, we reject the applicability of this character (i.e., surangular exposed, or not, on medial aspect of lower jaw) to taxa with a compound bone.

Another source of disagreement is the interpretation of the anatomy of *Pachyrhachis*. For example, Lee (1998) places great emphasis on the presence of a jugal in *Pachyrhachis* (as opposed to all other snakes) in his rebuttal of Zaher's (1998) criticism. We have re-examined the original material of *Pachyrhachis* as well as radiographs of the skull of the holotype, and concluded that a jugal is absent in this taxon. The element interpreted as a jugal by Lee and Caldwell (1998) is, in fact, the ectopterygoid, broken across the posterior tip of the maxilla. In all squamates which have a jugal with a suborbital process, the latter is a slender, anteriorly tapering process lining the ventral margin of the orbit. The putative jugal of *Pachyrhachis* is broadened anteriorly, as is the ectopterygoid of macrostomatan snakes, with which *Pachyrhachis* also shares the broad overlap of the ectopterygoid and maxilla.

Differences of opinion also exist with respect to search procedures. We agree with Lee (1998) that many of the characters shared by dibamids, amphisbaenians, and snakes might be due to convergence, resulting from character correlation due to burrowing habits (Rieppel 1984a). But instead of demonstrating this convergence empirically, Lee (1998) accepted the hypothesis of convergence due to character correlation as a valid *a priori* assumption in order to justify the arbitrary downweighting of those characters believed to be associated with the "fossorial ecomorph." It remains unclear why the threat of character correlation was used to justify the implementation of search procedures that would break the snakes away from the amphisbaenian–dibamid clade, while this latter clade is accepted on the basis of the very same characters of the burrowing ecomorph. As discussed by Gasc (1968), Rieppel (1984b), and Greer (1985), grouping dibamids with amphisbaenians results in homoplasy for those characters which dibamids share with other squamates such as gekkotans and scincomorphs. It also remains unclear why the characters believed to be associated with the "burrowing ecomorph" are downweighted in order to prevent "spurious" phylogenetic results, while the characters correlated with the development of intramandibular kinetics are not also downweighted in order to inspect their influence in the support of the mosasaur–snake clade. Lee (1998) treated a number of characters (110, 113 118, 119, 121, 123 124, 125, 126, 127, 130, 131, 135) as independent from one another, when in fact all of these reflect the development of intramandibular kinetics, and the correlated reduction of overlap between dentary and postdentary bones. Concerns that the intramandibular joint might have evolved independently in mosasauroids and snakes had been voiced earlier (Gauthier 1982), and distinct morphologies were confirmed in our recent study of the lower jaw of varanoids, mosasauroids, and basal snakes (Rieppel and Zaher, 2000b). For example, it is the surangular portion of the compound bone which supports the dentary in snakes, while in mosasaurs the dentary is primarily supported by the prearticular (Bäckström 1931; Gauthier 1982; pers. obs.). Also, the receiving part of the mobile splenial-angular contact is the splenial in mosasaurs, but the angular in snakes (Rieppel and Zaher 2000b).

Given a pattern of phylogenetic relationships showing terrestrial varanoids to be the sister-group of the (mosasauroid (*Pachyrhachis* (terrestrial snakes))) clade, the marine origin of snakes optimizes equivocally (Scanlon et al. 1999). The hypothesis of a marine origin of snakes therefore not only requires *Pachyrhachis* to be the most basal snake, but *Pachyrhachis* must also be accepted as an "excellent example of a transitional taxon" (Scanlon et al. 1999, p. 128) from a process point of view. This hypothesis cannot be maintained in view of the macrostomatan features shared by *Pachyrhachis* (Rieppel and Zaher 2000b; Zaher 1998) such as the elongate and posteriorly free-ending supratemporals, the elongate posterior dentigerous process of the dentary (the latter bone shows a single mental foramen only), the morphology of the palatine, the extensive ectopterygoid-maxillary overlap, the morphology of the postorbital-parietal contact (a postfrontal is absent), the presence of a long and slender shaft of the stapes, the presence of a posteriorly projecting opisthotic paroccipital process, and the posteroventrally sloping quadrate. Our re-analysis of the data set presented by Lee (1998) furthermore found strong support for a sister-group relationship of snakes with the amphisbaenian-dibamid clade (see also Estes et al 1988; Hallermann 1998).

We do recognize, as does Lee (1998), that this signal is suspect because of the threat of convergence due to fossoriality. However, the solution to this problem is not the *a priori* downweighting of characters believed to be correlated with the fossorial ecomorph, but the search for additional empirical evidence in a continued test of that hypothesis of relationships (Forstner et al. 1995; Reeder 1995).

Acknowledgments.—We have greatly profited from discussions with Richard Etheridge, Nicolas Fraser, Darrel Frost, Maureen Kearny, Arnold

Kluge, and Mark Norell, in the development of our research and ideas on snake phylogeny. This research is supported in part by grant no. 98/00064-7 from FAPESP (Fundação de Amparo à Pesquisa de São Paulo) to the senior author.

Further Evidence for Mites as Tertiary Prey in the Gastrointestinal Tract of Snakes and Frogs

ROD DOUGLAS
Department of Herpetology, National Museum
P.O. Box 266, 9300 Bloemfontein, South Africa
e-mail: reptile@nasmus.co.za

Although mites appear to be infrequently reported in reptile diet studies (Douglas 1992b; Schoener 1968; Schoener and Gorman 1968), in amphibian diet studies the occurrence of mites is far

more common (Dimmitt and Ruibal 1980; Norton and MacNamara 1976; Simon and Toft 1991). In many of these studies the occurrence of mites has been interpreted as them being part of the diet, when often the identification of mites is inadequate for the inferences and assumptions being made (Douglas, in preparation).

Van Dijk (1997) speculated that mites found in the gastrointestinal tracts of the snake *Psammophylax rhombeatus* could have originated from frogs, and not shrews, as was stated by Douglas (1992a). In the study by Douglas (1992a), information was presented that was part of a broader, more detailed, microscopic study on the diet of *P. rhombeatus* (Douglas 1992b). It would therefore be difficult to draw conclusions, similar to those made by Van Dijk (1997), from the former, without having consulted the latter. Van Dijk (1997) further speculated that mites in the gastrointestinal tracts of frogs, of which he found no evidence, might occur through the frogs ingesting their own molted skin. As a consequence of these assumptions, further clarification on mites as tertiary prey items in the gastrointestinal tracts of snakes and frogs is presented.

From 55 *Psammophylax rhombeatus* gastrointestinal tracts microscopically examined by Douglas (1992a), 20% contained free-living soil mites (Subclass Acari, Superorder Actinotrichida, Order Oribatida [N = 21]; and Superorder Anactinotrichida, Order Mesostigmata [N = 6]; classification after Evans 1992). The Orders were represented by eight genera: *Scheloribates, Brachioppia, Mikizetes, Passalozetes, Zygoribaula,* and *Mycobates*. These genera can be referred to as free-living soil mites which feed largely on live and decaying plant material, and are distinctly macrophytophagous, microphytophagous or, a combination of the two, panphytophagous. Although some mesostigmatid mites are known to be predatory, this is usually limited to prey which they can overpower, for example, nematodes and small arthropods (Evans 1992). None of the eight genera recorded by Douglas (1992a) was zoophagous, parasitic, or aquatic, and Evans (1992) did not mention any of these genera as being associated with frogs in any way. Being free-living soil mites would tend to rule them out as eating molted frog skin, or occurring on frogs.

In the gastrointestinal tracts of *Psammophylax rhombeatus*, 27 mites were recorded and accounted for 7.2% of identifiable items (N = 19) (Douglas 1992b). Only one species of anuran was recorded, *Cacosternum boettgeri* (N = 3). All the *C. boettgeri* were found in the same *P. rhombeatus* specimen and accounted for 1.8% of the occurrence of items (Douglas 1992b). Douglas (1990) further microscopically examined the remaining gastrointestinal tract of one of the three frogs and identified four major groups of insects (Coleoptera, Hemiptera, Chrysomelidae, with the bulk being Formicidae of the genus *Trinervitermes*), but no mites were found. This provided further evidence that the mites were not associated with the frogs.

As the shrew *Suncus varilla* was the primary prey of *P. rhombeatus*, representing 51% of prey species, a sample of 25 shrew gastrointestinal tracts also were examined. It was found that 43% of individuals contained oribatid mites. These mites were not at all damaged (e.g., through mastication) and were found only in association with earthworms (Douglas 1992a). Analysis of Churchfield's (1984) results on the diet of the shrew *Suncus araneus* showed a 53% correlation between the occurrence of mites and earthworms, a 65% correlation between the occurrence of mites and gastropods, and a 76% correlation between the occurrence of earthworms, gastropods, and mites (Douglas 1992a). The undamaged state of the mites and the aforementioned correlations tend to indicate that mites were not part of the diet of shrews, but were tertiary prey items incidentally ingested by the earthworms and gastropods.

The many assumptions and inferences in the literature, such as acariphagy, and which are based almost entirely on the occurrence of mites in the gastrointestinal tracts and not on any feeding observations, is the basis of a separate paper (Douglas, in preparation). Considering the evidence presented here, it is not clear how Van Dijk (1997) came to the conclusion that Douglas (1992a) did not consider frogs as an alternative source of mites.

On the other hand, Van Dijk (1997), without any evidence or references, put forward an alternative scenario of mites feeding on molted frog skin, which was then ingested by the frog. This scenario was based on an observation that ostracods occurred in the gastrointestinal tract of the aquatic frog *Xenopus laevis*, and that ostracods had been observed attacking the skin of *Kassina senegalensis* tadpoles (Van Dijk 1977). It may be asked whether the ostracods were actually feeding on the skin, or on the skin secretions? If ostracods and molted skin were found together throughout the gastrointestinal tract of *Xenopus laevis*, even as far as the rectum (Van Dijk 1997), this would clearly imply that neither were digestible items. If neither were digestible, then along with other indigestible prey remains such as insect exoskeletons, it would be very difficult to determine with any certainty whether the ostracods were specifically associated with the molted skin. That Van Dijk (1997) found ostracods in folds of the frog's ingested skin could also be explained by prey remains being shuffled and mixed while passing through the gastrointestinal tract.

There are other possible logical explanations for the occurrence of ostracods in the gastrointestinal tract of *Xenopus laevis*. The occurrence of ostracods would be analogous to indigestible mites found in gastrointestinal tracts of reptiles and amphibians, and the question would arise as to why the frogs would deliberately consume indigestible prey items such as ostracods? Because *X. laevis* is an aquatic species which feeds by hyobranchial pumping action (sucking in food and water and then expelling the water), ostracods could have incidentally been sucked up with other food items. This is highly probable because *X. laevis* is a scavenger and a predator (Lambiris 1989), and will consume almost any available food, including carrion, on which the ostracods could have been feeding. Alternatively, the ostracods could just as well have been incidentally ingested by other prey items and be of a secondary nature.

It was largely as a result of this type of inconclusive evidence that time was spent backtracking on the occurrence of mites in the *Psammophylax rhombeatus* gastrointestinal tracts. All the mite genera identified by Douglas (1992a) were free-living soil mites and very unlikely to be associated with frogs in any way. It is of course probable that certain mites may well utilize molted frog skin as part of their diet, but apparently not in this instance. At this stage it would appear that Van Dijk would have to look at other mite species to substantiate his alternative scenarios.

On the Status of the Coral Snake *Micrurus nigrocinctus* (Serpentes, Elapidae) in Belize, and its Northernmost Distribution in Atlantic Middle America

PETER J. STAFFORD
The Natural History Museum
Cromwell Road, London SW7 5BD, UK
e-mail: pjs@nhm.ac.uk

In listing *Micrurus affinis alienus* (= *M. diastema sapperi*) from Belize, Schmidt (1941) made reference to a specimen in the Zoologisches Museum, Berlin, that fell entirely outside the definition of this species. The snake is said to have originated from "Corozal Island, British Honduras," with no other source stated except "Wien." Schmidt described it as having "very well developed supra-anal tubercles," and noting that this character was otherwise wholly absent in the coral snakes from the area, he suspected some confusion of data. Neill and Allen (1959), however, suggested that the locality cited by Schmidt might be Isla Corozal or Isla Corosalito, variant names for a station on the Rio Hondo in Orange Walk District [Belize], and that the snake in question might be *Micrurus nigrocinctus*. In a subsequent paper, Neill (1965) described a specimen of *Micrurus nigrocinctus divaricatus* (Hallowell) from Gallon Jug, a locality also in the Rio Hondo drainage of Orange Walk District, since when specimens of *Micrurus* purportedly attributable to this taxon have been collected in Belize on a number of other occasions.

Micrurus nigrocinctus divaricatus is an exceptionally variable coral snake otherwise known from central and northern Honduras (Roze 1967, 1970, 1996). Populations from this region are in many features similar to *M. diastema* and also examples of the other nominal species of *Micrurus* reported from Belize, *M. hippocrepis* (Peters). During an assessment of variation in Belizean material of the genus *Micrurus* for the purpose of compiling a guide to the reptiles of this country (Stafford and Meyer 2000), it became apparent that specimens were attributable only to *M. diastema* and *M. hippocrepis*, and that, as suspected by Schmidt (1941), the errant individual with supra-anal tubercles from "Corozal Island" almost certainly originated elsewhere. It also emerged that the combination of characters described by Neill (1965) for the Gallon Jug *Micrurus nigrocinctus divaricatus* is at variance with the definition given for this taxon, and more like that exhibited by some *M. diastema*. It is the purpose of this paper to determine the status of these two specimens, and to suggest that the reported occurrence in Belize of *Micrurus nigrocinctus* has been based on confusing examples of *M. diastema* and *M. hippocrepis*. The northernmost distribution of *Micrurus nigrocinctus* in its Atlantic versant range is also discussed.

Information on the current understanding of the presence of *Micrurus* in Belize, including a comprehensive list of distribution records, has most recently been provided by Lee (1996). *Micrurus diastema* occurs almost countrywide, except on the offshore islands and perhaps in the extreme south, and in virtually all habitats. *Micrurus hippocrepis* has a restricted distribution in the more mesic southern lowlands and Maya Mountains, and *M. nigrocinctus* is known from a small number of localities scattered generally throughout the country as a whole. The list of locality records given by Lee (1996) for *M. nigrocinctus* is partly inaccurate in that it includes a series of *M. hippocrepis* described by McCoy (1970) from Middlesex, Stann Creek District [UCM series and CM 48010] (Lee, pers. comm.). Notwithstanding this, however, Lee (1996) cited 6 other records of *nigrocinctus* from Belize [mi 39 on Western Hwy. (MCZ 152577); Caracol (photograph); upper Raspaculo River Basin (Stafford, 1991); Gallon Jug (Neill, 1965); Guinea Grass Rd. ca. 4 mi S Northern Hwy (CM 105735); Stann Creek (USNM 24906)].

Micrurus nigrocinctus, *M. diastema*, and *M. hippocrepis* are tricolored, single-banded coral snakes that resemble each other also in habitus, scutellation, and some finer details of color pattern. In the region concerned, all three species are highly variable (Campbell and Lamar 1989; Fraser 1973; Lee 1996; Roze 1996; Wilson and Meyer 1972, 1985). Supra-anal tubercles are present in adult male *nigrocinctus*, and this is perhaps the most unambiguous distinguishing character in that it is lacking in *diastema* and *hippocrepis*. From populations of *M. nigrocinctus* in northern Honduras, the area geographically nearest to Belize from which examples of this species are otherwise available, *diastema* and *hippocrepis* may be further differentiated by utilizing combinations of various scale and color pattern features (Table 1). Significant among these is the proportional number of divided and undivided subcaudal scales; in *M. nigrocinctus*, the subcaudal scales are usually all divided, whereas a sizable proportion of those in most *diastema* and *hippocrepis* are entire. Also of note is the con-

dition of the nuchal ring and corresponding number of black body rings. In *M. nigrocinctus*, the nuchal ring is usually complete, of more or less the same length dorsally and ventrally, and in examples with fewer than 19 black body rings, up to 2 dorsal scale lengths distant from the posterior tips of the parietals. In *diastema*, it is either interrupted or narrowly constricted ventrally, and involves at least the posterior tips and usually a larger proportion of the parietals. The anterior margin of the nuchal ring in *M. hippocrepis* is occasionally posterior to the parietals, but in these individuals is incomplete (laterally in four specimens examined and ventrally in one). *Micrurus hippocrepis* is further distinguishable from most *nigrocinctus* in its conspicuous lack of black pigment on the scales of the red rings. The red scales of this species may be dusky in appearance or edged with a dark border, whereas, in most geographically proximate populations of *nigrocinctus*, black pigment is present either in the form of conspicuous, uniformly distributed spots, coalesced blotches, or medially-oriented accessory rings (exceptions include 5 specimens from Lancetilla and La Lima, Dept. Atlántida, Honduras, in which the red rings are immaculate). Some *M. diastema* and *M. hippocrepis* have a pale spot on the snout that may be restricted to the rostral or involve as much as the internasals, adjoining margins of the prefrontals, nasals, and the anteriormost supralabial. Among specimens of *M. nigrocinctus* examined, however, this condition is apparent only in one (MCZ 32010; Lancetilla, Depto. Atlántida, Honduras), and it is a feature not otherwise associated with the species.

On the basis of these features, all but two of the specimens of *Micrurus* from Belize may be allocated to either the common species of the region, *M. diastema*, or *M. hippocrepis*. Of the two exceptions, one is the specimen from "Gallon Jug, Orange Walk District" tentatively referred by Neill (1965) to *M. n. divaricatus*. The combination of characters described for this individual, which I have been unable to locate and examine for myself, disagree in several notable respects with the definition given for *divaricatus*. The other, a male from "Corozal Island" with well developed supra-anal tubercles, is the same as that originally suspected by Schmidt (1941) as not having come from Belize. It thus would appear necessary to examine in greater detail the status of these particular specimens.

ZMB 26384 (Corozal Island, British Honduras).—As originally suggested by Neill and Allen (1965), this specimen is referable to *Micrurus nigrocinctus*. It has a snout–vent length of 492 mm and a tail length of 88 mm, and there are 198 ventrals, 49 subcaudals (all divided), and 1+1 temporals on each side. Supra-anal tubercles are well developed. The black head cap is regular in outline and does not extend posteriorly onto the parietals; the black nuchal ring is complete, between 4 1/2–5 dorsal scales long, and involves the posterior tips of the parietals. There are 19 other black body rings, of which 4 are incomplete ventrally, and these vary from 2–2 1/2 dorsal scales in length. The red rings have faded completely in preservative and the original distinction between these and the yellow rings (assuming the latter were present in life) is no longer discernible; black pigment on the scales of the "red" rings is limited to small, more or less uniformly distributed dots. There are 6 black rings on the tail, ranging between 5 and 6 dorsal scales in length; the pale (yellow?) interspaces range between 2 1/2–3 1/2 scales long. Ventrally, the pale rings are immaculate, with black pigment present on the mental and anterior infralabials only.

The collection locality of ZMB 26384, as given in the Zoologisches Museum catalogue and cited by Schmidt (1941), is "Corozal Island, British Honduras." The other source quoted, "Wien," apparently refers to the collector, and it has been brought to my attention (courtesy of R. Günther) that in the Zoologisches Museum archives is a letter written by Wien dating from the 1880's in which the origin of the specimen (and a *Leptophis mexicanus*, ZMB 26385) is stated as the island of "Cozumel." This is assumed to be a reference to the island of that name located north of Belize off the coast of Quintana Roo, Mexico. Given that neither of these species are known to occur on Cozumel, however, and only *M. diastema* has been recorded from the adjacent mainland (Lee 1996), the likelihood of ZMB 26384 originating from this locality seems remote. It is apparent from his letter that at least some of Wien's specimens were collected in the Corozal area of Belize, and in light of this it is possible that "Cozumel" has been corrected subsequently or otherwise changed to "Corozal." Another possibility is that the specimen came from All Pines, a locality south of Belize City at the mouth of the Sittee River, where the majority of Wien's collection appears to have originated [for reasons unknown, the source of these, as given in the Zoologisches Museum catalogue, is "Beguiella, Carosall" (R. Günther, pers. comm.)]. The fact that no other *M. nigrocinctus* has been forthcoming since, either from these particular areas or elsewhere in Belize (Neill's report notwithstanding), however, suggests that there has most probably been some other fundamental confusion of data. Wien's letter is one of two filed in the ZMB archives under "Briefe Wien, Bestan Zoologie Sig: SII."

WTN 2856 (Gallon Jug, Orange Walk District).—Neill (1965, pp. 111–112) described this specimen as "a female; total length 317 mm, tail length of 47 mm. Dorsal scale rows 15, ventrals 212, subcaudals 49. Black rings 10 on body, these rings 5 1/2 to 8 scales long. Each black ring with yellow borders, each yellow ring about 2 1/2 scales long. Scales of red interspaces uniformly tipped with black, but no other black pigment in the red areas. Tail with 4 black rings separated by yellow interspaces. All rings complete and regularly transverse. Snout completely black; a yellow band across back of head extending anteriorly to posterior margin of eye." Allocating it tentatively to *Micrurus nigrocinctus divaricatus* (Hallowell), Neill (1965) remarked that the specimen (hereinafter referred to by its field number, WTN 2856) agreed with this taxon in ventral count and its long yellow rings, but disagreed in having a high subcaudal count and in the distribution of black pigment in the red zones, as well as in having a low number of black rings.

With respect to the number and length of its black body rings, WTN 2856 is particularly unusual. Roze (1996) gave a range of 11–24 rings for a sample of 121 *Micrurus nigrocinctus divaricatus*, and described these as usually 3–4 dorsal scales and 2–4 ventrals in length. It may be the case that the distinctive length of the body rings is an expression of the relatively low number of rings in this specimen, or that the range in ring length specified includes the nuchal ring, which in snakes of the genus *Micrurus* is typically longer than the other black body rings. In 31 *M. nigrocinctus* examined by me for the purposes of this review (Table 1), the black body rings do not exceed 5 dorsal scales in length, and the nuchal ring does not extend longitudinally for more than 6 dorsal scales and 4 ventrals (one specimen).

Another peculiarity of WTN 2856 is its high number of subcaudals, which is inconsistent with the known range of female *M. nigrocinctus* [32–43], *M. diastema* [32–45], or *M. hippocrepis* [36–42] (Roze 1996; see also Table 1). Taken with the proportional length of the tail (calculable as 14.8% of the total length), it seems more likely that the specimen is a male. The number of ventrals indicated falls within the range of male *M. diastema* from Belize [198–212], but is notably higher than the maximum recorded for a male *M. nigrocinctus divaricatus* [206] (Roze 1996).

Perhaps also significant is that the color pattern described by Neill (1965) for WTN 2856 is evident in no other specimen of *Micrurus* examined from Belize. *Micrurus hippocrepis* occasionally has 10 black body rings or fewer, but these are invariably narrow (1–3 dorsal scales), and dark pigment on the red dorsal scales is either absent, limited to small, sparsely-distributed dots, or confined to the leading edges of occasional scales. The number of black body rings exhibited by specimens of *M. diastema* from Belize is 18–33. In this particularly variable species, however, the

TABLE 1. Comparative external features of *Micrurus nigrocinctus* from northern Honduras [data combined with that of Roze (1996) for *M. n. divaricatus*] and Belizean *M. diastema* and *M. hippocrepis*. *Notes:* [1]counts made using method of Dowling (1951); [2]terminal spine not included; [3]nuchal ring and a black ring enclosing vent (where present) included; [4]black tip less than one half the width of the other black rings not counted; [5]specimens with 1+1 on one side and 1+2 on the other scored as having a 1+2 arrangement. Specimens exhibiting characteristics intermediate between *M. diastema* and *M. hippocrepis* are not included.

Presence (% frequency occurrence) and character of black pigment distribution on red dorsal scales	Usually present (84.4%); uniformly distributed, irregular, or suggestive of accessory bands		Present (100%); uniformly distributed, irregular, or suggestive of accessory bands		Usually absent (57.6%) or limited to small, sparsely-distributed dots/ marginal fringes of occasional scales, or scales dusky	

body rings range from 1.5–6 dorsal scales in length, and the yellow rings may be up to 2 dorsal scales long. Black pigment distribution within the red rings is typically irregular, although in some specimens is uniformly distributed with a well-defined spot on the tip of each scale. Many (61.3% of those examined) have a completely black snout. There is a particular resemblance between WTN 2856 and examples of *Micrurus diastema* allocated to *M. d. alienus* (Werner). An exceptionally similar specimen (USNM 24891, Yucatán, Mexico; male) has 11 black rings on the body, 4.5–7.5 dorsal scales long (nuchal ring included), yellow rings ca. 2 dorsals long, 4 black tail rings, uniformly distributed black tipping on the scales of the red rings, and a completely black snout. *Micrurus d. alienus* has not been reported from Belize, although it is known from the adjacent Guatemalan department of El Petén (Campbell 1998), and also intergrades with *M. d. sapperi* in southern Quintana Roo (Roze 1996). In consideration of this, and the discrepancies outlined above concerning the character of its color pattern and the number of ventral and subcaudal scales, it is suggested that WTN 2856 represents an example of *Micrurus diastema*, albeit a rather peculiar one.

Discussion of geographic distribution.—The northernmost distributional limit of *Micrurus nigrocinctus* in the Atlantic versant, as represented by specimens of known provenance and denomination, appears to be the Sula Plain area of Depto. Cortés, northern Honduras. Specimens from this locality are cited by Wilson and Meyer (1972, 1985). Schmidt (1933) listed *M. n. divaricatus* from the lowlands of eastern Guatemala, but did not elaborate on the source of his information, and Stuart (1963) included only the Pacific versant *M. n. zunilensis* in his Guatemalan list. No examples of *M. nigrocinctus* from eastern Guatemala appear to be available, and neither has recent exploration produced specimens or other evidence of the occurrence of this species in the region (J. A. Campbell, pers. comm.). A specimen in the Museum National d'Histoire Naturelle, Paris, labeled from "Guatemala" with no other locality data [MNHN 6082], is representative of the Pacific versant population. Given the proximity of eastern Guatemala to the department of Cortés, Honduras, however, it is possible that *nigrocinctus* may eventually be confirmed from this area. On the same basis, its occurrence in Belize, particularly in the relatively unexplored Maya Mountains, is also not inconceivable. From a biogeographical viewpoint, however, it is of some significance that the species has not been reported from El Petén (Campbell 1998; Campbell and Vannini 1989), with which southern Belize has greatest affinity, and that the respective herpetofaunas of southern Belize and northern Honduras are not more alike. Considering the short distance between southern Belize and northern Honduras, the proportion of species shared by these two regions is lower than might be expected (Stafford and Meyer 2000), a situation that may be a reflection of the area's geological history.

Acknowledgments.—My appreciation is extended to Rainer Günther (Museum für Naturkunde der Humboldt-Universität zu Berlin) and Linda Ford (American Museum of Natural History, New York) for their kind assistance in checking collection records on my behalf, Larry Wilson (Miami-Dade Community College) and an anonymous reviewer for appraisals of the original manuscript, and to the following individuals for the loan of specimens: Linda Ford (American Museum of Natural History), John Wiens and Stephen Rogers (Carnegie Museum of Natural History, Pittsburgh), Alan Resetar and Cassy Redhed (Field Museum of Natural History, Chicago), Frank Burbrink (Louisiana State University Museum of Natural Sciences, Baton Rouge), Robert Henderson (Milwaukee Public Museum), John Cadle (Harvard Museum of Comparative Zoology, Cambridge), Annemarie Ohler (Museum National d'Histoire Naturelle, Paris), Colin McCarthy (The Natural History Museum, London), Ronald Crombie and Robert Wilson (Smithsonian Institution National Museum of Natural History, Washington), Rosanne Humphrey (University of Colorado Museum, Boulder), Rainer Günther (Museum für Naturkunde der Humboldt-Universität, Berlin), and Samuel Turvey (University of Oxford). For information concerning the location of several specimens, grateful thanks are also due to Janis Roze.

Seasonal Activity of the Scarlet Snake, *Cemophora coccinea*, in Florida

e-mail: sullivd@gfc.state.fl.us

The semifossorial *Cemophora coccinea* apparently exhibits a unimodal peak of surface activity and is inactive during the cooler months, even during warm spells (Gibbons and Semlitsch 1987). However, Ernst and Barbour (1989) speculated that *Cemophora* might be active year-round in Florida during mild years. During a drift-fence survey in Tate's Hell Wildlife Management Area (WMA), Franklin County, Florida, USA, we observed anomalous cool-weather activity by *Cemophora coccinea* at one drift-fence array. In order to ascertain monthly activity patterns of *Cemophora*, we compiled additional data from throughout Florida that sampled most months of the year (Table 1).

Excluding the data from Franklin County, 96.4% of all *Cemophora* (N = 330) in Florida were captured between April and August, and 74.2% between May and July (Table 2). There is no apparent trend for more southerly populations in peninsular Florida to have a longer activity season than northern populations, although a specimen was captured on 16 November in Hernando County and on 16 December in Martin County. In subtropical Dade County, *Cemophora* were captured on roads from May through July (Dalrymple et al. 1991) and were observed eating *Terrapene carolina* eggs at night from 1 April through 16 June (Dickson 1948). Drift-fence studies in South Carolina yielded a similar window of activity to studies in Florida, with all *Cemophora* being captured from April through October (Gibbons and Semlitsch 1987). However, peak *Cemophora* activity in Florida (May–June) occurred one month earlier than in South Carolina (June–July). Specimens have been collected from 19 April through 7 November in Virginia (Mitchell 1994), but these records may have included animals collected from underground brumation sites. A *Cemophora* collected in Mississippi on 10 December from under a piece of bark near a swamp (Allen 1932) may have been brumating.

The observed May–July peak in surface activity for *Cemophora* probably corresponds with increased activity associated with the breeding season and foraging for food. Although *Cemophora* have been recorded taking a variety of prey, reptile eggs appear to be preferred (e.g., Brown 1979; Dickson 1948; Minton and Bechtel 1958; Neill 1951; Palmer and Tregembo 1970; Williams and Wilson 1967), and peak oviposition for most squamate and some turtle species in Florida occurs from April through July. *Cemophora* have been recorded moving 600 m in 26 days (Nelson and Gibbons 1972), and such long-distance movements may be necessary to

find seasonally limited food resources which are spatially dispersed.

We collected data on *Cemophora* activity from 12 drift-fence arrays in scrub and mesic flatwoods habitats in Tate's Hell WMA from April 1998 through March 1999. Traps were open 10–13 days each month except for September. Tate's Hell WMA accounted for 75.0% of all *Cemophora* captures (N = 20) outside the April–September period (Table 2). All 15 captures of adult *Cemophora* from October–February came from only a single array, which accounted for 15.2% of captures (N = 46) during the remainder of the year (Table 2). This array was situated in open, sand-pine scrub ca. 1 km north of the Gulf of Mexico (29°47'43"N, 87°46'59"W).

We cannot explain the atypical dormant-season activity exhibited by *Cemophora* at one array in Tate's Hell WMA. Individuals were not marked, but several were responsible for the observed activity, because up to three specimens were trapped at one time. The winter was drier than normal; thus, *Cemophora* were not flooded from subterranean retreats by rising water tables. Ephemeral and permanent wetlands were situated ≥ 20 m from the array, and open, sandy areas at the site may have been used by nesting turtles. It is possible that *Cemophora* were feeding on eggs of "winter"-nesting *Deirochelys reticularia* and *Kinosternon subrubrum* during a time of the year when they are normally inactive. *Cemophora* are almost exclusively nocturnal (Gibbons and Semlitsch 1987; Nelson and Gibbons 1972; Palmer and Tregembo 1970), and nights in northern

Florida are typically too cool for reptile activity from October through March. However, apparently emaciated *Cemophora* have infrequently been observed engaging in diurnal surface activity during the winter in Gadsden County, Florida (S. P. Christman, pers. comm.), suggesting that the *Cemophora* trapped in Tate's Hell WMA from October through February may have been active during the daytime. It is possible that this one array at Tate's Hell WMA was situated near a hibernaculum or other important winter resource for *Cemophora*, and the individuals we trapped were displaying normal low-level activity during warm weather in winter.

Acknowledgments.—We thank L. C. Branch, D. G. Hokit, J. B. Miller, H. R. Mushinsky, W. W. Timmerman, and K. N. Wood for sharing their drift-fence data. P. E. Moler, J. A. Gore, and D.A. Wood reviewed earlier drafts of this paper. K. Setser, H. R. Mushinsky, and J. R. Mendelson III provided helpful comments on the manuscript. Surveys conducted in Gadsden, Franklin, Baker, Taylor, Marion, Hernando, Pinellas, Polk, and Highlands counties were supported by the Florida Fish and Wildlife Conservation Commission.

Available data concerning biology and aggressive behavior in species of *Phyllomedusa* come mainly from Colombia (Pyburn and Glidewell 1971), Uruguay (de Sá and Gerhau 1985), and Argentina (Laurent 1973). Pyburn and Glidewell (1971) and Laurent (1973) suggested that *Phyllomedusa hypocondrialis* is territorial, but a detailed study has not been conducted. This species has a wide distribution in South America (Frost 1985). We studied a population on the eastern border of its Amazonian distribution. Here we summarize the reproductive biology of this population and present data on territoriality from two breeding sites having different vegetation structure.

The study sites were two temporary ponds in open areas at the side of a main road at the Parque Estadual do Bacanga, São Luís (2°35'S; 44°15'W), Maranhão State, northeastern Brazil. These ponds differed structurally in terms of vegetation cover: a pond with widespread vegetation on its edge and interior (WVP), consisting of continuous tangled shrubs up to 1.7 m high; and a pond with marginal vegetation only (MVP), consisting of scattered shrubs and small trees, up to 2.5 m high. We collected data weekly from March to early July 1991, and between 1500 and 0300 h using a dim or red flashlight at night. We made preliminary observations in 1989, 1990, and January–February 1991 at the same and other sites. We marked calling sites and male positions

throughout the night with colored ribbons or clothes-pins. We recorded vocalizations, but we failed to obtain sonagrams due to technical problems. At MVP, where physical interactions between males were not observed naturally, we caught a calling male in a shrub, and released him 15 cm from another calling male in a neighboring shrub. We experimentally examined amplexus behavior in nature by separating an amplectant male and releasing him 10 cm from the female. We repeated this procedure, then also released another calling male 10 cm from the same female. In the laboratory we observed the development of five egg clutches and reared tadpoles until metamorphosis.

The breeding period (January to June) coincided with the rainy season. In January 1991 at MVP males called from inside the thick vegetation and we could frequently hear their vocal interactions. At the end of March they moved closer to the water line and called from exposed sites on the vegetation edge. We found egg clutches only after March.

Males called from 1745–0300 h. The advertisement call emitted by isolated males is composed of one note audible to the human ear. Upon the approach of a female, a male increased the calling rate. During the vocal interactions between males, a different note was emitted. This note was emitted by isolated males in response to playbacks. Upon the approach of a male into the territory of another male and during the wrestling bouts, both males emitted only these different notes.

During the first hours after sunset the males interacted vocally as they presumably established their territories since we did not find females or new clutches before 2300 h.

Males called from leaves or branches, either inside or near temporary ponds or more rarely, permanent ones, at heights of 0.4–3.5 m (mean = 1.4; SD = 0.9; N = 32) above the water. Generally, calling males moved to adjacent perches and changed their positions and postures. Thus, even on the same perch, males turned to call in different directions. Similar behavior was observed in *Agalychnis callidryas* and *Pachymedusa dacnicolor* (Pyburn 1970) and *P. hypocondrialis* (Pyburn and Glidewell 1971).

The calling male (N = 8) moved in a circle all night long. We considered this to be patrolling behavior. The area, about 1 m in diameter, usually patrolled by a male was considered to be its territory, since one patrolling male physically attacked another calling male that entered the area.

We observed calling males near call sites that had been occupied during the previous night. Our impression is that males return to the same territories in consecutive nights, although we did not mark the animals.

During the breeding season vocal interactions and fights between males in adjacent territories were common. We observed six fights at WVP. The typical agonistic behavioral sequence consisted of territorial calls and a fast approach, followed by a slow wrestle made up of head and leg pushing alternating with resting (Fig. 1). Wrestling bouts lasted from 10–60 min. Both males emitted only the different note during these bouts. In all encounters the winner was the resident male.

At MVP, the territories were not adjacent because of scattered vegetation, and each active male occupied one shrub. The interactions were strictly vocal, with the emission of both kinds of notes. In the experimental encounter, however, the aggressive behavior was similar to that described for WVP. After physical

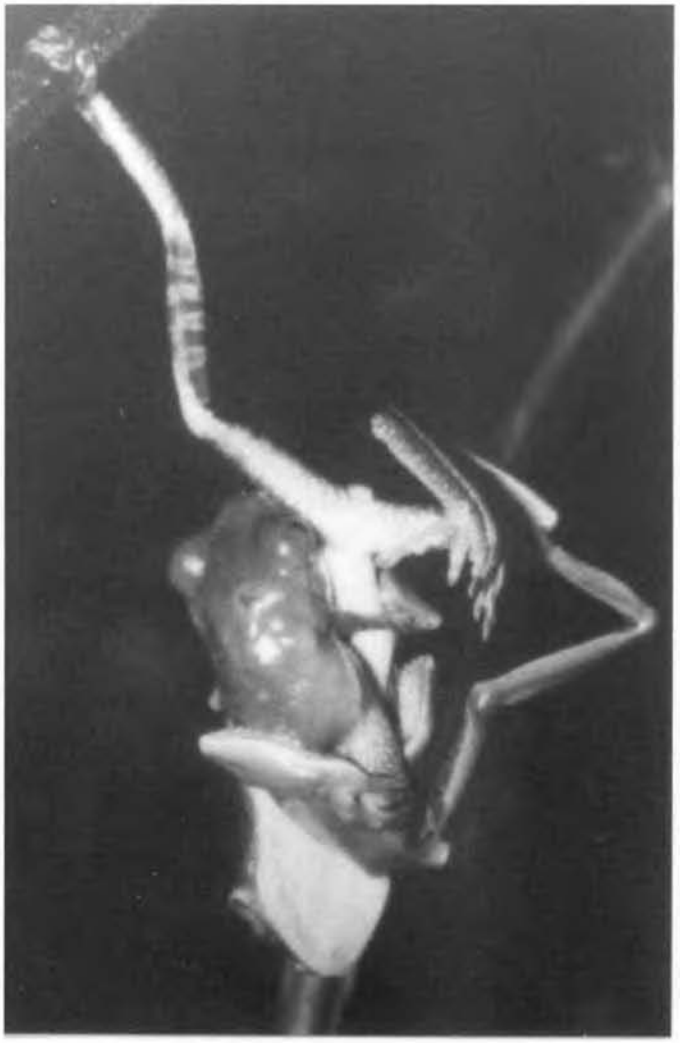

FIG. 1. Two males of *Phyllomedusa hypocondrialis* during a territorial fight, the resident grasping the branch. Photo by G. V. Andrade.

interaction, the intruder returned to its original territory in the neighboring shrub. We suggest that early in the breeding season before males approach the water line and clutches are deposited, each male, through aggressive behavior, establishes its territory in an isolated shrub or tree at MVP. Aggressive interactions in adjacent territories at WVP point out that resident males are intolerant of other calling males in the limits of their territories. Such behavior implies maintenance of spatial separation between males through vocalizations, as occurs in other species (Pyburn 1970; Wells 1977). Maintenance of inter-male space through vocalization, aggressive interactions, and patrolling behavior are characteristic of territoriality in *Phyllomedusa hypocondrialis*.

When we experimentally separated an amplectant male from the female, the female began walking in the direction opposite from the male. The male then started vocalizing, and increased the rate of advertisement calls. After that, the female stopped walking and the male walked in the direction of the female and jumped onto her back in axillary amplexus. When we released two males the intruder tried unsuccessfully to dislodge the original male from the female's back by inserting its head between the female's back and the original male's ventral region. The intruder then attacked the amplectant male by pushing and kicking its

opponent with its arms. The fight ended when the intruder moved away.

Oviposition followed by leaf folding behavior was similar to behavior observed by Pyburn (1980). Females oviposited on branches of shrubs or trees overhanging the ponds, and enclosed the egg masses in leaves. Two pairs were on herbaceous vegetation 15 and 90 cm above the water, respectively. Both amplectant females moved toward the petiole, and laid the eggs while undergoing abdominal contractions. The pair closed the leaf using their hind limbs and movements of their cloacae. We noted abdominal contractions of the male when its thigh was at right angles to its body. The male elongated and compressed its body against the female and then inserted its cloaca into the folded leaf. The movement of the pairs proceeded until the leaf was completely closed. Sometimes, during this behavior, the male emitted advertisement calls. In both cases the male released the female and resumed calling within 10 min after egg laying was completed. The female left the oviposition site after 20 min.

The clutches of *P. hypocondrialis* were laid on leaves that ranged between 2.1–6 cm wide (mean = 3.76 cm; SD = 1.02; N = 14), and 3.3–15 cm long (mean = 7.98 cm; SD = 3.22; N = 18). Generally the leaf was folded; when a leaf was too narrow, two leaves were joined together by the amplectant pair. Clutch size varied from 62–154 eggs per clutch (mean = 87.15; SD = 23.58; N = 13) and did not correlate significantly with leaf width ($r_S = 0.52$; $p > 0.05$).

The clutches were deposited from 5.5–210 cm (mean = 110 cm; SD = 59.6; N = 21) above the water. The water depth below the clutch sites ranged from 4–34 cm (mean = 18.04 cm; SD = 11.4; N = 12), and eggs were deposited from 24–120 cm (mean = 72.64 cm; SD = 34.37; N = 11) from the shoreline. In the laboratory (ca. 26°C) eggs hatched after 8 days and larvae metamorphosed after 43 days.

The simpler and less specialized reproductive pattern in Phyllomedusinae is exhibited by *Agalychnis callidryas* (Pyburn 1970), whose eggs are laid on open leaves with little or no male help other than fertilization. *Pachymedusa dacnicolor* also lays eggs on open leaves, but male assistance occurs (Pyburn 1970). *Phyllomedusa iheringi* (Ihering 1886), *P. trinitatis* (Kenny 1966), *P. distincta* (Castanho 1994), and *P. hypocondrialis* (Pyburn and Glidewell 1971; this paper) close the leaves with male assistance.

Acknowledgments.—We thank C. F. B. Haddad, J. P. Pombal, Jr., and L. M. Castanho for critical reading of the manuscript. J. W. Petranka, U. Caramaschi, W. E. Duellman, and three anonymous reviewers substantially improved the paper. A. d'Heursel and J. R. Lima helped with the translation of the text. We thank the PET/CAPES for grants to RHRM and AH.

The Extraction of DNA from Formalin-fixed, Ethanol-preserved Reptile and Amphibian Tissues

MARK E. CHATIGNY

e-mail; mchatigny@biology.usu.edu

Genetic studies are becoming a primary component of wildlife conservation. These studies are used to define the genetic structure of populations and provide estimates of genetic diversity. This information can aid in management of wildlife by providing a basis for the allocation of funds and prioritization of management activities for the preservation of genetic diversity.

An initial step in most genetic studies is the extraction of DNA from tissues. Once extracted, the DNA is often amplified using PCR (polymerase chain reaction) and analyzed by a variety of molecular techniques. PCR-based techniques require very small amounts of DNA, therefore it is not always necessary to extract the DNA from the tissues of living organisms. For example, DNA can be extracted from fur, shed skins, or scales.

Although DNA can be extracted from a variety of sources, if an organism is sufficiently rare or difficult to capture, as are many reptiles, it may be impossible to locate enough individuals. This highlights the desirability of using specimens from existing museum collections. These specimens are usually stored in ethanol after having been preserved initially with formalin. Formalin is a 1.3 M aqueous formaldehyde solution which has been used for preserving tissues almost since its development in 1865 (Fox et al. 1985). It hardens tissues without shrinkage or distortion by forming cross-linkages between the proteins (Fox et al. 1985).

The interaction of formaldehyde with DNA is not well understood, but there is evidence that cross-linkages are formed between the proteins and the DNA as well as between the strands of the DNA (Chaw et al. 1980; Chang and Loew 1994). The existence of these protein-DNA cross linkages has led to the belief that specimens fixed in formalin and stored in ethanol are, for the most part, unuseable for DNA analyses and, therefore, genetic analyses of museum collections have rarely been attempted (France and Kocher 1996).

Although extraction of DNA from formalin-preserved tissues is difficult, recent investigations have met with varying degrees of success. Medical researchers interested in genetic diseases were among the first to extract DNA from formalin-fixed, paraffin-embedded tissue sections, but the results were highly variable and dependent upon the fixation time and the storage conditions (Rogers et al. 1990; Forsthoefel et al. 1991). More recently, investigators have had greater success with the extraction procedures using a prolonged proteinase K digestion with times ranging from 24 to 50 h (France and Kocher 1996; Shiozawa et al. 1992). Some investigators have resorted to chemical means to break the protein cross linkages, adding DTT (Dithiothreitol) to the proteinase K digestion-stage (Johnson et al. 1995). France and Kocher (1996) reviewed the various extraction protocols using a rating system based upon the percentage of extractions that yielded a PCR product of the expected size. They determined that the most effective extraction protocols were those that utilized a prolonged digestion period, although the most successful protocol, developed by Shiozawa et al. (1992), was successful in only 66% of the extractions.

I have developed a modified protocol for the extraction of DNA from skin that can, in most cases, be rubbed from the bodies of formalin-fixed, ethanol-preserved specimens without damaging the specimens. This protocol has worked on both reptilian and amphibian specimens and has been used to extract DNA from specimens that were stored in formalin for extended periods of time. The protocol makes use of a prolonged proteinase K digestion, similar to that of Shiozawa et al. (1992), and also an additional chemical component, Dithioerythritol (DTE), to break the protein cross-links. Several other extraction protocols were tested along with this one, including some that used slightly different long digestion periods (France and Kocher 1996; Shiozawa et al. 1992) and some using additional chemical means to break the protein cross-linkages (Johnson et al. 1995) but none of them worked as well as the protocol using both methods. Extractions using this protocol yielded a quantity of DNA sufficient for amplification in 14 out of 15 repetitions, and the average size of the amplified product was approximately 700 base pairs.

Tissues were prepared for the extraction process by grinding them to a fine powder in liquid Nitrogen using a small mortar and pestle. Approximately 50 mg of ground tissue was placed in a 1.5 ml micro centrifuge tube along with 1 ml of STE buffer (0.1 M NaCl; 0.05 M Tris-HCl, pH 7.5; 0.001 M EDTA), 25 µl of 20 mg/ml proteinase K, 50 µl of 20% sodium dodecyl sulfate (SDS), and 2.5 µl of 20 mg/ml of DTE. The aggregate was gently mixed and then incubated in a gently shaking water bath for 24 h at 55°C. An additional 25 µl of proteinase K, 25 µl SDS, and 2.5 µl of DTE was then added and the mixture was placed back into the water bath for 48 h at 55°C. The mixture was then placed in a 15 ml centrifuge tube and subjected to two standard PCI (phenol, chloroform, and isoamyl alcohol in a ratio of 25:24:1) extractions, and two standard CI (chloroform and isoamyl alcohol in a ratio of 24:1) extractions. The aqueous layer was placed in a clean tube and one-tenth volume of 2 M sodium chloride was added. The mixture was precipitated with one volume of cold (–20°C) 95% ethanol and stored at –20°C overnight. Each tube was then centrifuged for 30 min at 7000 g and the supernatant was removed using a micro pipette. In most cases, there was no visible pellet so care was taken to avoid disturbing the liquid at the very bottom of the tube. The remaining liquid was evaporated in a convection oven for 2 h at 55°C. The pellet was resuspended in 50 µl of TE buffer (0.001 M Tris-HCl, pH 7.5; 0.0001 M EDTA). I attempted to establish the presence, concentration, and fragment length of the extracted DNA from each sample by size-fractioning the sample on a 1% agarose gel but I found that the concentration of DNA was often too low to produce a visible band. I therefore amplified all extraction products using an amplification profile specifically designed for samples with a low template concentration.

Primers used in PCR were designed to amplify the cytochrome *b* gene of mitochondrial DNA. These primers had been used extensively on samples from within the genus *Lampropeltis* and were known to amplify the specimens used for the study. The PCR reaction volume of 50 µl contained:
10 µl of template DNA, 5 µl reaction buffer (500 mM KCL; 100 mM Tris, pH 8.8; 15 mM $MgCl_2$; 30 mM DTT; 1 mg/ml BSA), 50 mM of each dNTP, 25 pmol of primers 462 (5'ACTTCAGGGTGCCCAAAGAATCA3') and 562 (5'TAAGCTATGGGGCTCATACC3') (Operon Technologies Inc. Alameda, California, USA), and 2.5 units of *Taq* DNA polymerase. The cycling profile included: melting for 1 min at 95°C , annealing for 2 min at 37°C, and elongation for 3 min at 72°C. The total number of cycles was 35.

The ability to extract sufficient quantities of amplifiable DNA from museum specimens could be of value to researchers working with rare or extinct organisms, and it may also be of some use to researchers wishing to compare individuals or populations on a temporal scale.

Acknowledgments.—I gratefully acknowledge the help of Chris Fillmore in developing this protocol and for his patience and advice. Jennifer Burbank assisted me with the study and spent many long hours in the lab. This project was funded in part by a grant from the Utah Division of Wildlife Resources to James A. MacMahon.

Mouse glue-traps have recently become a popular means of capturing lizards and other reptiles for ecological studies (Bauer and Sadlier 1992; Rodda et al. 1993; Whiting 1998). Previous technical notes have discussed glue-trap sampling on islands in the western Pacific (Bauer and Sadlier 1992; Rodda et al. 1993) and southern Africa (Whiting 1998). In this note we comment on the efficiency of glue-traps for sampling reptile diversity in the West Indies. In particular, we provide data concerning rates of capture and recapture, species sampled and missed by glue-traps, mortality of captured reptiles, accidental capture of non-target vertebrates, and the economics of glue-trap sampling.

All glue-trap sampling occurred in Los Haitises National Park and the immediately surrounding region in the Dominican Republic. The Los Haitises region is a karstic area on the southwestern border of Samana Bay that originally was characterized by broad-leaf humid tropical forest (Zanoni et al. 1990). The primary goal of our sampling was to determine the effects of human disturbance on lizard diversity (Glor et al., in review), but here we will concentrate strictly on the pros and cons of glue-trap sampling.

Our glue-trap sampling protocol involved thirty 10 x 10 m grids placed in nine different habitats. Each of these grids contained twenty Victor® mouse glue-traps (Woodstream Inc., Lititz, Pennsylvania 17543-0327, USA). These traps can be purchased in bulk from many commercial exterminators for US $0.25–$0.42 per trap. In each grid, five traps were placed in each of four microhabitats for a total of twenty traps per grid. Microhabitats sampled were: 1) open ground, at least 1 m away from the nearest tree; 2) ground at base of tree; 3) tree trunk or branch, 1 m above the ground; and 4) tree trunk or branch, 2 m above the ground. Ground traps were placed on bare soil or rock, while tree traps were stapled into position using a staple gun and 8–10 mm staples. An attempt was made to place the traps in five rows, each with a single trap in each microhabitat.

Traps were checked at least once every 24 h for the duration of the 120-h trapping cycles. Depending on the number of reptiles captured, it took two people 15–60 min to check traps, process and release animals, and replace damaged or missing traps. As has been reported previously (Rodda et al. 1993), the effectiveness of traps tends to decline with age, primarily as a result of exposure to the elements and accumulation of debris. In our study, wet or damaged traps were replaced regularly. Each trap was replaced approximately every 2.5 days during the course of a five-day trapping period.

FIG. 1. *Anolis chlorocyanus* in glue trap.

Most reptiles were released from the traps by loosening the glue around them with vegetable oil applied with a paintbrush (Bauer and Sadlier 1992; Rodda et al. 1993). Only large robust anguids (*Celestus stenurus* and *C. costatus*) could be released without oiling. All reptile species captured could be effectively removed without injury; though special care must be taken when removing small fragile-skinned lizards (e.g., *Sphaerodactylus*) as well as certain body parts of anoles such as the dewlap and tail. The toenail on the fourth rear digit was clipped to allow for identification of recaptures.

During ten weeks of sampling (spread over three trips) we ac-

TABLE 1. Rates of capture for each taxon sampled.

	Number Captured	Captured per Trap-hour
Anolis baleatus	19	0.00011
A. chlorocyanus	113	0.00067
A. cybotes	194	0.00115
A. distichus	866	0.00515
A. semilineatus	70	0.00042
A. spp.	15	0.00009
Celestus stenurus/costatus	81	0.00048
C. sepsoides	4	0.00002
Sphaerodactylus spp. (5 species)	38	0.00022
Antillophis parvifrons	4	0.00002
Epicrates striatus	6	0.00004
Tropidophis haetianus	1	0.00001
Total	1411	0.00840

TABLE 2. Success of traps in each different microhabitat. More trap-hours were accumulated in the open ground traps because one of the habitats sampled (active pasture) contained only open ground traps and no tree traps. Cost per lizard based on cost of $0.30 per trap and replacement every 2.5 days.

	Trap-hours	Lizards sampled	Lizards per trap-hour	Estimated cost per lizard sampled
Open ground	48,480	154	0.0032	$1.56
Tree base	39,840	306	0.0077	$0.65
1 m tree	39,840	462	0.0116	$0.43
2 m tree	39,840	489	0.0123	$0.41
Totals	168,000	1411	$\bar{X} = 0.0084$	$0.60

cumulated over 168,000 trap-hours (one trap set for one hour = one trap-hour). During this time 1411 reptiles representing 16 species were captured. Overall, traps captured reptiles at a rate of 0.0084 per hour or approximately one reptile every five days for a given trap. Because traps cost about US $0.30 and last an average of 2.5 days our cost per capture was approximately US $0.60.

The traps sampled 16 of the 20 reptile species known to occur in the Los Haitises region, based on available distribution records (Schwartz and Henderson 1991) and visual surveys that we conducted concurrent with glue-trap sampling (Table 1). No amphibians were captured, despite their abundance in and around the park, likely because of their moist skin. On several occasions frogs of the genus *Eleutherodactylus* were observed hopping onto and then off of the traps.

The reptile species known to occur in the region but never captured in traps included two primarily arboreal snakes (*Uromacer oxyrhynchus* and *U. catesbyi*), a fossorial blind snake (*Typhlops pusillus*), and the fossorial *Amphisbaena manni*. *Anolis* lizards dominated our samples, accounting for over 90% of captures (Fig. 1), while captures of snakes and small geckos were exceedingly rare (Table 1). Based strictly on capture rate per hour, a researcher seeking to capture a single individual of *Epicrates striatus* (rate = 0.00004 individuals per trap-hour) in a 24-h period would need to set 1000 traps. Though this suggests that glue-traps are a highly inefficient means of capturing certain species, the placement of our traps systematically targeted only a subset of available microhabitats. Additionally, the placement of our traps was random in that we made no attempt to target the locations that appeared most favorable as reptile shelters or basking sites.

Non-random targeting of specific habitats and microhabitats has the potential to considerably increase trapping success. For example, during the course of ten weeks of 'random' sampling only two individuals of *Sphaerodactylus samanensis* were captured (rate = 0.00001 individuals per trap-hour). However, on one occasion we placed 50 traps at the base of rock shelters in a habitat that appeared ideal for this species and recovered six individuals of *S. samanensis* in a 24-h period (rate = 0.005 individuals per trap-hour) increasing our success rate to 500 times that of random sampling.

Another form of selective trapping involves the placement of traps at the entrance to shelters or near basking sites where reptile activity has been observed (Whiting 1998). We used this technique with some success to capture *Sphaerodacytlus* that were observed running under rocks and *Celestus* that fled into cavities under tree roots. We only captured juveniles of *Anolis baleatus* and *Epicrates striatus*, suggesting that the adults of these species were either too large for the traps or did not occur in the microhabitats we sampled at sufficient densities.

The overall trapping success of 0.0084 reptiles per trap-hour masks finer scale variability in trapping success between traps placed in different habitats or microhabitats. Differences in trapping success in different habitats is discussed elsewhere (Glor et al., in review). Among the microhabitats sampled, traps in trees captured more than twice as many reptiles as traps on the ground (Table 2). The success of tree traps in our sample is undoubtedly the result of the overwhelming abundance of the arboreal anoles. Not surprisingly, previous reports suggest that success of tree versus ground traps depends on the specific reptile fauna of the area being sampled (Bauer and Sadlier 1992; Rodda et al. 1993).

Only eight lizards were recaptured during the course of our sampling. The reasons for this low rate of recapture are unclear and warrant further study. Although mortality following release is a possibility, a number of lizards that were maintained in captivity for several days following their capture appeared healthy and active. Other possible reasons for the low rate of recapture include: movement out of the trapping grid, avoidance of traps following capture, inability to stick to traps due to residual oil applied during the previous capture, and increased predation on previously trapped lizards.

One major drawback to glue-trapping is lizard mortality, which averaged 10.9% during our sampling. However, considerable variability in mortality existed between different habitats (range: 6–18.6%). Generally, mortality was higher in agriculturally disturbed or open sunny plots relative to forested plots. Although the cause of death was often unclear (32.5% of deaths), three identifiable factors (exposure [13.5%], ant predation [31.3%], and vertebrate predation [22.5%]) contributed to lizard mortality in traps. Ant predation was rare in most habitats except oil palm plantations and pastures. Based on the presence of rat hairs in a number of traps with dead lizards, the majority of vertebrate predation was likely caused by rats. However, mongoose hair was found on at least one occasion and two instances of snake predation and one possible case of attempted lizard predation were noted. In both cases of snake predation the predator was a juvenile *Epicrates striatus*. The case of suspected lizard predation involved shed scales of *Anolis baleatus*, which were found next to the body of an adult

male *A. chlorocyanus* with obvious bite wounds.

Although dead lizards were salvaged and preserved when possible, and these deaths are unlikely to seriously affect the reptile populations or the community as a whole, a reduction in mortality would clearly be desirable for future studies. More frequent checking of traps would probably reduce all forms of mortality. In the case of ants, a commercial ant repellent could potentially be applied around the margin of traps in habitats where ants are known to be problematic. In order to reduce mortality caused by exposure, traps should be placed in shaded areas when possible. If shade is unavailable or random sampling is required, traps should be placed on the underside of branches or could even be shielded from direct sun by a strategically placed leaf.

In addition to mortality, accidental capture of non-target animals was another problem associated with glue-trap sampling. Incidental capture of invertebrates occurred in nearly all traps, but captures of non-target vertebrates were rare. Non-target vertebrate captures included eight species of birds and two species of mammals. A total of eleven bird captures occurred during the course of our sampling. Therefore, the rate of bird capture for a single trap was approximately one bird every 640 days. Live birds were released from the traps with a paintbrush and oil. Bird species captured were: oven bird (*Seirus aurocapillus*), black-throated blue warbler (*Dendroica caerulescens*), broad-billed tody (*Todus subulatus*), bananaquit (*Coereba flaveola*), Hispaniolan woodpecker (*Melanerpes striatus*), ruddy quail dove (*Geotrygon montana*), and black crowned palm tanager (*Phaenicophilus palmarum*). The two migrant species (black-throated blue warbler [*Dendroica caerulescens*] and ovenbird [*Seirus aurocapillus*]) were caught only in the winter months. On a number of occasions, feathers from Hispaniolan lizard cuckoos (*Saurothera longirostris*) were found in traps although a cuckoo was never actually caught. These cuckoos might have been attracted to the traps by captured lizards; indeed, on several occasions cuckoo feathers were found on a trap along with a lizard which had beak-shaped bruises on its abdomen. These probably represent failed predation attempts.

Mammal captures were of less concern because the traps affected only two introduced species. Rat hair and the terminal portion of rat tails were found in traps regularly and on at least one occasion a small tuft of mongoose hair was found in a trap. On only one occasion was a live, immature rat captured in a trap.

Although unfortunate, we considered incidental captures of vertebrates rare enough to justify continued trapping in the Los Haitises region. However, traps should never be used in areas with abundant ground foraging or bark gleaning birds, native small mammals, or domestic animals. The potential for high rates of incidental captures suggests that trapping grids similar to ours could probably not be used in the mainland tropics. Trapping should never be conducted in areas where rare or threatened species are likely to encounter traps.

Overall, we found sticky traps to be an effective method for surveying reptile diversity in the West Indies. The majority of reptile species present in the Los Haitises region can be trapped; including large numbers of certain species, as well as several species that we were unable to locate during visual surveys. Additionally, the monetary cost associated with our glue-trap sampling, about US $0.30 per trap and US $0.60 per capture, was fairly reasonable. However, several serious drawbacks associated with the use of these traps may limit their utility for future ecological studies in some situations, particularly in the mainland tropics.

Acknowledgments.—We thank George Zug and Tom Fritts for providing information on how to acquire and use glue-traps. Mike Combs provided many hours of assistance in the field. The United Nations Global Environment Facility (GEF) and the Cornell International Institute for Food Agriculture and Development (CIIFAD) provided financial and logistical support. Permits and support in the field were provided by Dirección Nacional de Parques and Departamento de Vida Silvestre in the Dominican Republic. José Ottenwalder provided logistical support in the Dominican Republic.

Funnel traps originally described by Imler (1945) and simplified by Fitch (1951) have been used in many terrestrial (Fitch 1951, 1963; Greenberg et al. 1994; Imler 1945; Vogt and Hine 1982), arboreal (Fritts et al. 1989; Rodda and Fritts 1992; Savidge 1987) and aquatic (Adams et al. 1998; Calef 1973; Carpenter 1953; Fraker 1970; Richter 1995; Riley and Bookhout 1990) field studies. Some aquatic studies (Calef 1973; Richter 1995) have used modified funnel traps with air chambers to prevent suffocation. Traps in these studies have been attached to buoys and placed on the surface, or attached to rods in the ground and placed at varying levels in the water column. However, typical methods for aquatic captures have involved placing unmodified traps half-submerged (without any flotation aid) along the shoreline (Fraker 1970; Keck 1994) or fully submerged (Adams et al. 1998; Carpenter 1953) on the water bottom. Two similar, significant problems exist when using these placements. Any reptile or adult amphibian (with the exception of paedomorphic salamanders) will drown in an underwater trap if not tended to often enough. Depending on changes in water level, animals captured in traps half-submerged run the risk of drowning, desiccating, or over-heating. Here we describe a safe and easy funnel trap modification for humane use in the field.

Eelpots (Cuba Special Manufacturing, Fillmore, New York, USA) measured 60.5 cm long and 22.5 cm in diameter (terminal funnel openings measured 4 cm in diameter), and were made from 0.5 cm gauge hardware-cloth (Fig. 1). Two pieces of Styrofoam measuring 30 cm x 6 cm x 5 cm (L x W x H) were attached with locking, 22.7 kg tensile strength nylon ties (Thomas and Betts Corporation, Memphis, Tennessee, USA) to the middle, opposing sides of each eelpot. A third nylon tie was attached in the middle for easy manipulation of the traps. The Styrofoam blocks were attached so the traps floated half-way out of the water. Two pieces of nylon rope, 1.5–2 m in length, were also attached to opposite sides of each eelpot. Traps were placed in the water and were aligned to facilitate entry of animals following along edges of the shoreline or of vegetation (Fig. 2). Each trap was tied to nearby vegetation or to stakes in the ground with enough play in the rope to compensate for fluctuating water levels. Traps were left out continuously for at least 10 days and were checked daily. During periods of non-trapping, plastic cups were used to close funnel openings and prevent captures. Diameter of funnel openings, dimensions of Styrofoam, placement of Styrofoam on traps, and length of rope can be easily altered as needed. Under normal conditions, the Styrofoam will support the weight of any captured animal and will last at least one year without need for replacement. Eelpots were the greatest expense (US $15/trap), but the additional materials were of negligible cost (~ US $1.50/trap). Funnel traps can be built from aluminum window screen (Greenberg et al. 1994) as a less expensive, but more labor-intensive alternative.

Fraker (1970) described his unmodified, aquatic funnel traps as "relatively inefficient," reporting a 2.3% success rate (2.3 snakes caught per 100 trapping-days) in 79 days of trapping northern water snakes (*Nerodia sipedon sipedon*) in a fish hatchery and the surrounding ponds and streams. Our modified traps are currently being used in the fifth year of an ongoing study of giant garter snakes (*Thamnophis gigas*) in deep and shallow water central California ponds, sloughs, and irrigation canals. During the first 79 days of trapping in 1997, we report a 3.7% rate of trap success. Although trap efficiency is relatively low in both studies, it is important to note that trap success was not negatively affected—and was actually greater—when using this modified design. Trap success may be improved if the traps are baited (Keck 1998) or when used in combination with other methods (Adams et al. 1997) such as drift fencing (modified from Lutterschmidt and Schaeffer 1996).

According to Adams et al. (1998), funnel traps detected the most species of all sampling methods compared, required the least effort to use, and was the only technique to detect presence of small populations. In a review of various aquatic sampling methods, Adams et al. (1997) felt the strongest reason for using funnel traps was that the skill and experience of the user has very little influence on results. Drawbacks noted by those two papers were that funnel traps capture few adult amphibians, potential trap locations are not maximized, and the problem of trap mortality. During the

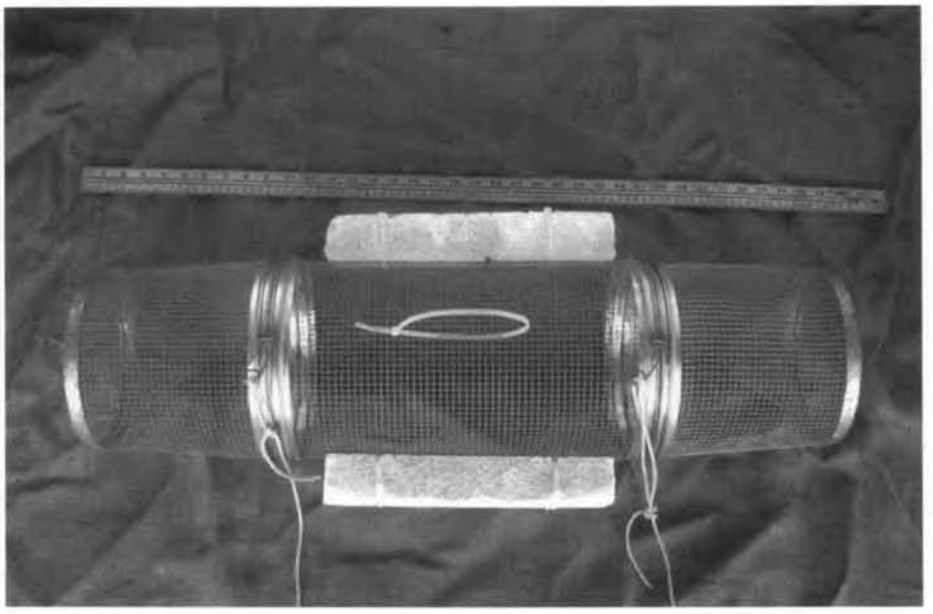

FIG. 1. Eelpot modified for placement on water surface.

FIG. 2. Modified trap in a marsh along edge of vegetation.

second year of our *T. gigas* study (the only year amphibian captures were recorded), our traps caught twice as many adult bullfrogs (*Rana catesbeiana*, N = 160) as larval bullfrogs (N = 81). Furthermore, our design allows for sampling an increased range of aquatic habitats. Future conservation work will depend on the quality of sampling done now. Being able to survey additional areas will provide a more accurate documentation of species presence and distribution. Finally, trap mortality is avoidable. No amphibian or reptile has died in our traps due to drowning, desiccation, or other trap-related causes (several bullfrogs have been partially consumed by crayfish, *Procambarus* and *Pacifastacus* spp.). Our trap design is appropriate for use in studies where animal safety is important or where habitats (i.e., stream banks with steep slopes) preclude deployment of unmodified funnel traps.

A considerable amount of literature is available on the effect of fire on vertebrates (deBano et al. 1998; Quinn 1994; Whelan 1995). Amphibians have been less studied than reptiles and mammals, but it is thought that they have a high survival rate to the direct effect of fire because they find shelter underground and in very wet areas that are inflammable (Friend 1993; Kirkland et al. 1996; Mushinsky 1985). Arboreal anurans, however, are not expected to burrow and have been suggested to suffer a higher mortality than the ones that do burrow (Friend 1993; Gillon 1983).

Phyllodytes luteolus (Wied) is a hylid that spends its entire life among bromeliad leaves (Bokermann 1966; Giaretta 1996). Males call and defend territories in the plants and females lay one to three eggs per leaf axil (Giaretta 1996; Weygold 1981). Teixeira et al. (1997) found densities of 0.2 (N = 36 rosettes) to 2.3 (N = 40 rosettes) adult frogs per bromeliad rosette near São Mateus, state of Espírito Santo, Brazil.

We compare the effects of a fire on the terrestrial bromeliad *Vriesea neoglutinosa* (Mez) and the frog *Phyllodytes luteolus*. The study site is a 210-ha open area surrounded by Atlantic Forest, with sandy soil, few trees, scattered shrubs, and strong dominance of *V. neoglutinosa* on the ground (Rocha et al. 1996). It is called Nativo do Parajú and it is located adjacent to the Reserva Florestal da Companhia Vale do Rio Doce, Linhares County, state of Espirito Santo, Brazil. The area has not been used for agriculture, and there are no records of previous burning.

In July 1993, before the fire, Giaretta (1996) studied the use of the same bromeliad (treated in his study as *Vrisea procera*) for reproduction by *Phyllodytes luteolus* at the same site. He sampled rosettes in the central part of the Nativo do Parajú, trying to approximate a random selection of rosettes. He defoliated 85 rosettes and found 14 adult male *P. luteolus*, 13 females, and 7 juveniles. Eggs were found in 15 rosettes and tadpoles in 25, and occupied rosettes had at least one egg or tadpole in 12.5% of the leaf axils. Adult males called during the afternoon but mainly at night (Giaretta, pers. comm.).

On 14 March 1995, a fire of unknown origin burned the whole area to its boundary with the forest. In April 1995, Rocha et al. (1996) determined that the fire burned more than 99.9% of the existing *Vriesea neoglutinosa* rosettes in the area to some extent, but the actual survival rate was not clear as the plants may recover from small, hidden unburned parts. They also sampled the remains of the plants and estimated that the population size of *V. neoglutinosa* was 2.6 million individuals before the fire.

In July 1995, four months after the fire, we visited the same site and heard only seven or fewer males calling on three different nights in the entire area. Large numbers of males were known to call in July in the area before the fire (Giaretta, pers. comm.). There was a rainy period immediately before the beginning of our study, and during the study we observed about ten individuals calling every night in an unburned, small group of bromeliads (11 x 22 m) near our lodge (8 km from the study area). To determine if the frogs were absent or just silent, we sampled the same area previously studied by Giaretta (1996). We repeated his methods of isolating a rosette with a net to prevent the escape of frogs and defoliating it while examining the leaves for the presence of frogs, tadpoles, and eggs. The precise location of the area sampled by Giaretta (1996) in the central part of the study site was unknown. To conduct a comparison with Giaretta's pre-fire data, we defined the central area as all points farther than 100 m from the forest. This area is flat with apparently homogeneous vegetation cover (Alves et al. 1996; Giaretta 1996; Rocha et al. 1996). In this central area, we sampled 5 randomly positioned transects (50 x 0.6 m). Three additional transects were sampled perpendicular to the limits of the burned area to determine if rosettes at the edge of the forest were functioning as refugia for the frogs. Transect sampling was opted to permit calculation of density estimates, to detect gradual change at the boundary between the burned area and the forest, and to facilitate future comparisons with data from site monitoring. We determined height, diameter, number of green leaves and volume of water stored among the axils of each rosette and searched for animals among the leaves while removing them. We only sampled rosettes that had the tip of the central axis within the limits of the transect. We also ignored rosettes that had the tip of the central axis closer than 1 m from a sampled rosette to avoid underestimating the fauna if the sampling procedures would cause animals to flee from neighboring rosettes.

Vriesea neoglutinosa were distributed in aggregates and even the remains of the heavily burned rosettes were sufficiently preserved to allow counting. In addition to measuring and defoliating the rosettes in the transects, we surveyed survival in all the rosettes of the aggregates crossed by transects. We considered each rosette to be an individual. Survivors were defined as rosettes that had green leaves. The limits of an aggregate were gaps >1 m between the tips of the leaves of any two adjacent rosettes.

The five transects crossed 32 aggregates of *Vriesea neoglutinosa* that contained a total of 885 rosettes. The weighted mean survival of rosettes in the aggregates was 30.6% (range 13.5–100%). In the transects, we examined 46 rosettes and found no *Phyllodytes luteolus* adults, juveniles, tadpoles, or eggs. The tips of most leaves were burned. The number of green leaves per rosette and the volume of water contained among leaves were smaller than the estimates by Giaretta (1996) before the fire (mean ± SD [N], two sample *t* test: no. leaves/rosette, 18.8 ± 5.3 [32] before fire, 14.6 ± 4.0 [46] after fire, $p<0.001$; volume water (ml) among leaves/rosette, 734.2 ± 207.8 [31] before fire, 11.9 ± 17.8 [46] after fire, $p<0.001$). At the edge of the forest and the limit of the burned area, fewer plants were dead and they were larger and had more leaves than the ones in the central area (Fig. 1). We analyzed 36 rosettes at the forest edge but found no *P. luteolus*.

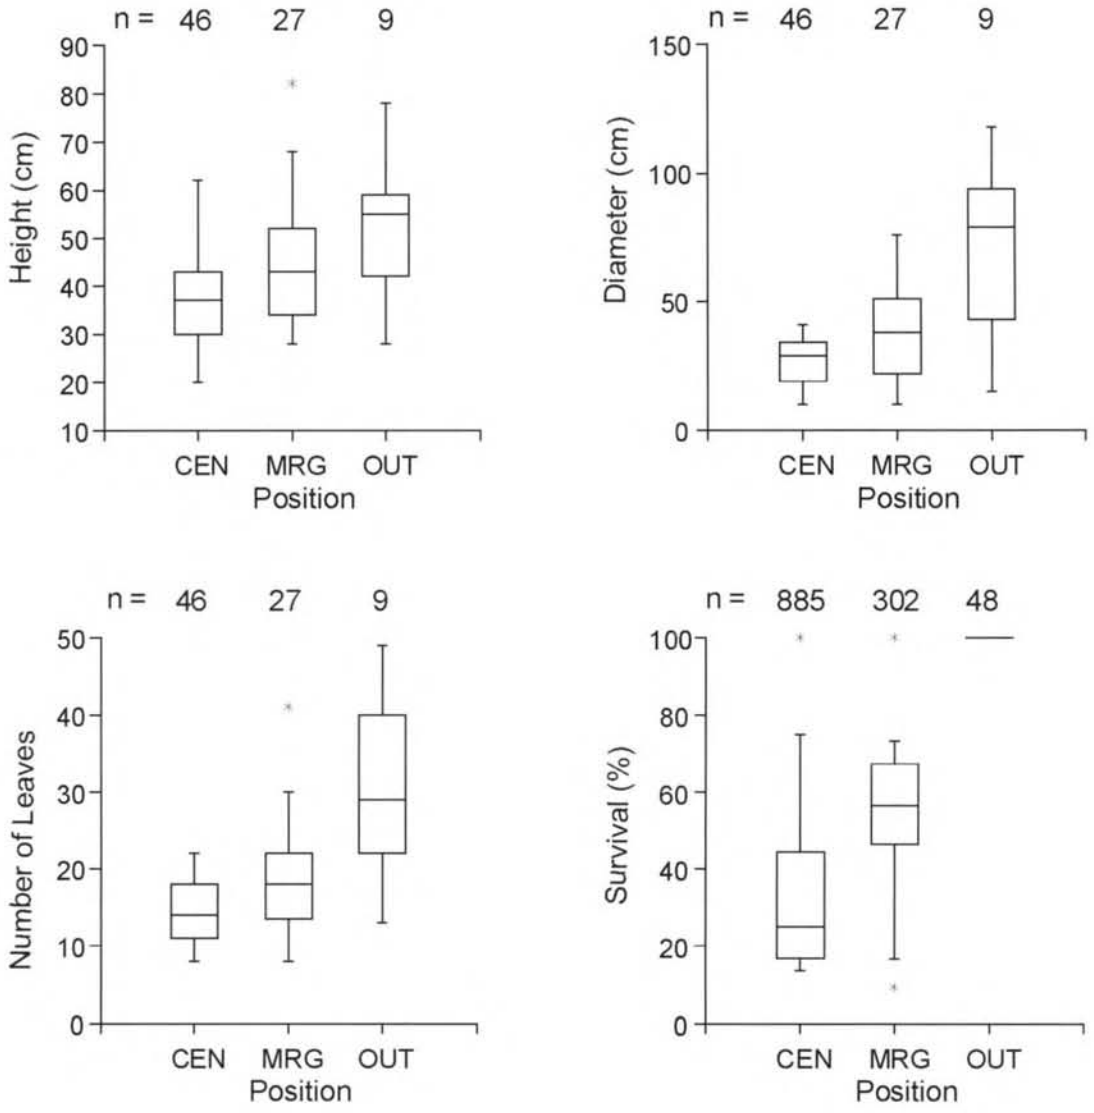

FIG. 1. Characteristics of rosettes of the bromeliad *Vriesea neoglutinosa* four months after a fire, in relation to their position in the burned area. CEN = center of the burned area, MRG = margin of the burned area, OUT = outside the burned area.

Studies on the effects of fire in amphibian assemblages have produced disparate results. Friend (1993) reviewed the literature on the effects of fire on Australian anurans. He found that most species were burrowers and were inactive during the dry season, when fires are more frequent. Those species were not significantly affected by fire. Arboreal frogs (*Litoria*) and species that were active in the dry season (*Limnodymastes dorsalis* and *Myobatrachus gouldii*) were found with higher frequency in long-unburned sites. Mushinsky (1985) studied the herpetofauna of sandhills in Florida in areas repeatedly burned at different time intervals. He did not find a decrease in abundance or diversity in the areas burned more frequently. Kirkland et al. (1996) sampled burned and unburned areas in central Pennsylvania and found more amphibians in the burned area. *Bufo americanus* accounted for most of the captures and the authors suggested that the difference may have been an artifact produced by a burst of activity after a rain. In African savannas, most species are inactive during the dry season and retreat to burrows or wet areas, so that the direct effects of fire are negligible (Gillon 1983). Populations are denser, however, and experience smaller annual fluctuation in savannas that have not been burned for long periods.

Our data indicate that *Phyllodytes luteolus* suffered a stronger population reduction than *Vriesea neoglutinosa* in the Nativo do Parajú. The fire might have killed relatively more frogs than bromeliads, or the microenvironment in the survivor rosettes might have been unsuitable for the frogs after the fire. *P. luteolus* may use bromeliads other than *V. neoglutinosa* for reproduction but it is selective to characteristics of individual rosettes (Eterovick 1999). Teixeira et al. (1997) found that *P. luteolus* avoids rosettes with less than 100 ml of water, and that they are more common in rosettes in open areas (mean ± SD: 2.68 ± 2.80; N = 60 frogs or tadpoles per rosette) than in rosettes shadowed by shrubs (0.53 ± 0.94; N = 36). Their results indicate that no part of our study area offered ideal conditions for recolonization because the plants that were alive in the burned area had little water and the ones that were not burned were shadowed under the forest canopy.

This study supports the suggestion by Friend (1993) that arboreal anurans may be strongly affected by fire. His suggestion also

may apply to other organisms associated with bromeliads. Various species of protozoans, worms, insects, crustaceans, spiders, and amphibians are commonly found in neotropical bromeliads that hold water and some of these animals may depend on the plant to complete their life cycle (Laessle 1961; Madeira et al. 1995; Oliveira et al. 1994). We found only spiders and ants among the leaves of the bromeliads affected by fire. In unburned rosettes, however, we found ants and spiders but also worms and larvae of beetles, mosquitoes, and dragonflies. This indicates that the fire also affected the invertebrate fauna found in the rosettes. It is not conclusive, however, because the effect of fire could be confounded with the effect of the forest. All the rosettes that escaped the fire were located at the border of the forest, where they were shaded and organic matter originated from the forest canopy accumulated among their leaves.

In many open areas dominated by grass, fire is common and native plants often have high survival and rapid recolonization (Coutinho 1982). However, the effect of fire on areas dominated by ground bromeliads is largely unknown (Alves et al. 1996). One year after our study, Alves et al. (1996) surveyed the bromeliads and found that the surviving individuals fully recovered their size and weight. The density, however, was only 28% of the density before the fire, about the same percentage that we detected as surviving rosettes (30.6%). This indicates that no substantial formation of new rosettes occurred in the first 18 months after the fire. Donnelly (1989) studied population dynamics of *Dendrobates pumilio*, a frog that uses bromeliads for tadpole development in Costa Rica. She artificially increased the availability of bromeliads in an area and detected increased immigration, recruitment, and survival of frogs. She concluded that the availability of bromeliads is a constraint for population size in *D. pumilio.* If the same is true for *P. luteolus,* recolonization in the Nativo do Parajú might be dependent on a successful recovery of the bromeliad population.

Long term monitoring in the area is necessary to determine if the pre-fire abundances of bromeliads and associated fauna will recover, and how long the process will take. Understanding the effects of fire in this community is necessary for proper management of land in relation to manmade fires, which are common in the region (Teixeira et al. 1997).

Acknowledgments.—We are grateful to A. A. Giaretta, R. E. Gresswell, K. LeVering, D. H. Olson, M. J. Ryan, R. A. Seigel, and an anonymous reviewer for reviewing the manuscript, and to the Companhia Florestal do Vale do Rio Doce, Fundação MB and CNPq for logistic support and fellowships. This study was conducted during the field course in ecology of the MS in Biology (Ecology) Program at Unicamp.

Status of the Northernmost *Sceloporus grammicus* Population

CELIA GARCÍA-PRIETO
MORGAN R. McKELLER
and
MICHAEL JAMES McCOID
Department of Biology, Campus Box 158, Texas A&M University, Kingsville, Texas 78363, USA
e-mail (MJM): mccoid@isni.net

Although the mesquite lizard (*Sceloporus grammicus*) is native to much of northern Mexico, including extreme southern Texas, the full extent of the species' range in Texas is apparently conjectural. Smith (1946) figured the range as the lower Rio Grande

Valley extending north along the coast to include Cameron, Willacy, and Kenedy counties to approximately Kleberg County. Conant (1958) showed only the Rio Grande Valley as the range of *S. grammicus* but noted an isolated record approximately in Kleberg County. Conant (1975) similarly pictured the lower Rio Grande Valley as the range in Texas but also included a disjunct population approximately in Kleberg County. Garrett and Barker (1987) showed the range of *S. grammicus* in Texas as similar to that presented by Conant (1975). In contrast, Dixon (1987) regarded the lower Rio Grande Valley as native range and stated that the population in Kleberg County and record in Refugio County were accidentally introduced. Axtell (1988) portrayed the lower Rio Grande Valley as native range and classified all other Texas records (including Cameron County) as extralimital or questionable. Most recently, Conant and Collins (1991; 1998) re-established the native range in Texas as the lower Rio Grande Valley extending north coastwise to Kleberg County, similar to that originally figured by Smith (1946). Evidence for uniting the disjunct population in Kleberg County with the lower Rio Grande population on a map is lacking; we are unaware of any specimens of *S. grammicus* from either Kenedy or Willacy counties (see Axtell 1988).

Despite the fact that *Sceloporus grammicus* is apparently missing from Kenedy and Willacy Counties, appropriate habitat occurs in this region. There is almost continuous scrub forest of mesquite (*Prosopis* sp.) and oak (*Quercus* sp.) extending north from the city of Raymondville (Willacy County) to the city of Kingsville (Kleberg County) (ca. 75 linear miles). An historical reference to habitat in this disjunct region of Kenedy and Willacy counties described this area in the 1830's as a "wilderness of plains...covered with small forests of oaks" (Berlandier 1980). Proudfoot and Beasom (1997) describe large tracts of land in Kenedy County as having a mesquite and oak forest at least 80 years old. This information suggests a continuity of habitat for at least the past 160 years. Presence of apparently suitable habitat, however, does not ensure the presence of *S. grammicus* in this distributional gap and suggests the absence of the species is real and not a collecting artifact. Recently, Proudfoot and Beasom (1997) analyzed the feeding habits of diurnal owls from Kenedy County and recorded nine species of lizards as prey, including four phrynosomatids, but not *S. grammicus*.

Axtell (1988) stated that *Sceloporus grammicus* had established "incredibly dense" populations in Kingsville by the early 1960's but had almost all inexplicably disappeared by 1973. The earliest specimen from Kleberg County catalogued in the Texas A&M University–Kingsville (TAIU) research collection was collected in 1965.

We endeavored to resurvey previous collecting sites in Kingsville to verify the continued presence of *Sceloporus grammicus* in Kleberg County. Locality data associated with some *S. grammicus* deposited in the TAIU collection were precise enough that we were able to visit eight specific sites that had yielded specimens 10 to 33 years earlier. Searches were also conducted in mesquite and oak groves at additional localities not previously identified as *S. grammicus* sites. Searches were intensively conducted during the month of April when daily high temperatures ranged between 27 and 35°C. No *S. grammicus* was sighted and we were unable to verify the recent presence of *S. grammicus* in Kleberg County at any site. Although we are aware of the dangers of relying on visual surveys to assess population parameters of reptiles (Rodda 1993; Henke 1998), one of us (MJM) has experience collecting *S. grammicus* in northern Mexico and has periodically surveyed appropriate habitat in Kleberg County since 1994 and failed (except as noted below) to observe any *S. grammicus*.

We are aware of two sightings in Kleberg County in recent years, but no specimens were obtained. One of us (MJM) moved into a Kingsville house in August 1993 that was landscaped with a small group of junipers (*Juniperus* sp.) and ashes (*Fraxinus* sp.). A group of three to five adult *S. grammicus* lived in these trees until July 1995 at which time they were replaced by two *S. olivaceus*. The second sighting (by MRM) was of a single adult lizard in October 1997 in southern Kleberg County.

Although we doubt that the species is extirpated in Kleberg County, we suspect that the population continues to decline and that the species never occurred in Kenedy and Willacy Counties. We support Dixon (1987) and Axtell (1988) in that the population in Kleberg County and record from Refugio County should be regarded as extralimital. We also predict that the population of *S. grammicus* in Kleberg County eventually will be extirpated.

HERPETOLOGICAL HISTORY

Editor's Note.—With this first issue of 2000, we initiate a new section of *HR*, Herpetological History. Articles suitable for publication may address any aspect of the history of herpetology—the parameters are purposely broad so as not to limit, a priori, the scope of material. Manuscripts should be directed to the editor (RH).

The Writings of Sherman Bishop: Part I. *The Salamanders of New York*

TODD HUNSINGER
Biological Survey, New York State Museum
3140 Cultural Education Center, Albany, New York 12230, USA
e-mail: Hunsitod@hvcc.edu

Sherman Bishop's (1941) classic monograph *The Salamanders of New York* is arguably one of the most influential herpetology works of the twentieth century. His peers immediately realized the impact of Bishop's work, for the reviews were very complimentary. Hubbs (1942) wrote "Experimental embryologists and other biologists...will join herpetologists in their gratitude to Dr. Bishop for his full compendium of published and original information on the natural history of the salamanders which occur in New York." Schmidt (1943) wrote "The work as a whole forms an extraordinarily satisfactory account of a rich and varied section of the North American salamander fauna." Bishop's detailed species accounts included original observations and data on mating behavior, egg masses and deposition, development from egg to maturity, habits, and habitat. At the time of Bishop's death, former student Arnold B. Grobman described *The Salamanders of New York* as "probably the most complete report on a group of animals from a state ever assembled" (Grobman 1952).

Although *The Salamanders of New York* was not printed until June 1941, Bishop had worked steadily on its development during his tenure as Zoologist at the New York State Museum, a position he held from 8 May 1916 to 31 August 1928 (Stoner 1937). Bishop completed herpetological surveys of Allegany State Park (Bishop 1927a) in addition to publishing on the herpetofauna of Albany County (Bishop 1923) and the mudpuppy (Bishop 1926). Field studies were completed on Long Island, Lake George, and in Putnam County. Bishop showed a strong interest in furthering his knowledge of the life history of salamanders and in educating others as well. In 1926 he prepared two exhibits for the State Museum (Bishop 1927d), *Life History group of Spotted and Jefferson Salamanders*, and *Habitat group of the Hellbender*, in which "the group will show a section of stream bottom with the nest and eggs of the Hellbender and guardian parent engaged in protecting the nest from enemies bent on foraging." All of this work was conducted in an attempt to gain the knowledge to complete a much larger project that Bishop had envisioned, the salamanders of New York.

A lack of support for the State Museum by the State Legislature and Board of Regents hindered Bishop's attempts to complete *The Salamanders of New York* and other projects much earlier than 1941. Bishop's own typewritten draft of the Report of the Zoologist (Bishop 1927d) for the 1926 fiscal year reveals his desire to complete this project, as well as his frustration over a lack of institutional support for his research and projects. Bishop reported:

> "Project No 2 The Salamanders of New York: Their Life Histories and Habits. Scope: In this study it is proposed to present a complete account of the life histories, habits and general development of New York salamanders."

Under the heading of 'Finances,' Bishop (1927d) wrote:

> "The most urgent need of the zoologist is for sufficient funds to bring to completion studies which have been carried out during the past eight or ten years. The report on, 'The Life History of New York Salamanders' has been delayed because of the impossibility of securing the services of an artist to complete the series of watercolor drawings. Funds for traveling expenses have been insufficient to enable the zoologist to complete the study on New York amphibians and reptiles."

This frustration came after Bishop had outlined what was needed to complete the project in earlier memos to Charles Adams, the Director of the State Museum (Bishop 1927b,1927c). *The Salamanders of New York*, which was two-thirds complete (Bishop 1927b) would require "$500.00 for the completion of color plates and about $150.00 for travelling expenses" (Bishop 1927c; see Fig. 1).

A lack of funding is evident again in Bishop's correspondences with close friend and colleague Francis Harper of the Boston Society of Natural History. In a letter dated 6 January 1928, Bishop writes, "My chief interest in accepting an offer to talk in Boston, if the opportunity presented itself, is this: It would give me an opportunity to examine specimens in the collection at Cambridge. Our funds for out-of-state travel are exhausted each year before I get a chance at them and cannot afford to take the trip unless I could make at least part of my expenses."

The minimizing of zoological research and publications was not unique to Bishop's tenure at the State Museum. During his 62-year affiliation with the State Museum, geologist James Hall (Museum Director 1870–1894) established it as one of the leading geological museums in the world (Fakundiny 1987). The tenure of zoologists during the early 20th century was rarely more than 2–3 years. During the 38 years from 1888 to 1926, the biologists produced a total of 29 museum publications, or less than one per year (Fakundiny 1987). The appointment of Charles Adams as director of the State Museum on 1 May 1926 marked the first time the Museum Director had not been a geologist.

Whether Bishop's tone denotes a final frustration with a perceivably unresponsive institution or an attempt to persuade the new director, it is evident that he was not satisfied with the speed at which he was able to work. Under the heading of 'Progress of Work,' Bishop (1927d) wrote:

> "Project No. 2. The Salamanders of New York: Their Life Histories and Habits. Status: The study of a considerable number of species has been brought nearly to completion. Certain critical stages of several species remain to be studied and will necessitate field work [sic] in various selected areas. This project has been held up for several years because funds have not been made available to secure the services of an artist competent to make the necessary color drawings.
>
> A considerable number of line drawings, color drawings and photographs have already been prepared. Plans: With few exceptions, the study of New York species may be carried out in the

vicinity of Albany. For the field study of the marble and Tiger salamanders it is necessary to visit Long Island; for the Mudpuppy and Hellbender, western New York."

Bishop's talents had not gone unnoticed in the herpetological community. He was approached on three separate occasions to join the staff of the American Museum of Natural History at a substantial increase in salary. G. Kingsley Noble visited Albany in 1922 to persuade Bishop to come to the American. The last offer from the American came in February of 1924 when Roy Chapman Andrews offered Bishop a position to work with the Asiatic collection, a project that already included noted herpetologist Clifford Pope. In all three incidents, Bishop declined the enticing offers from the American, "in part at least, because of promised salary increases that never materialized" at the State Museum (Bishop 1928).

Bishop left the State Museum in August 1928, to accept a teaching position at the University of Rochester. This moved him closer to his childhood home and increased his annual salary from $2,750 to $4,000, with the prospect of additional money from summer employment (Bishop 1928). In a letter to Francis Harper dated 14 March 1928, Bishop stated, "By April 4th I expect to be able to announce a change in my activities. I am contemplating a move to a much better position." In a response dated 19 March 1928 Harper wrote, "Aside from its financial drawbacks, however, it seems that your present position is quite a strategic one, and I shall certainly be sorry to see you leave it." After Bishop announced that the position had materialized, Harper wrote (7 May 1928), "There will be, I am sure, no small gain to you in peace of mind."

After leaving the State Museum, Bishop continued to press ahead with his manuscript on salamanders, believing that publication was imminent. The announcement of his appointment at the University of Rochester that appeared in the Rochester Democrat and Chronicle (1928) was entitled "U.R. Instructor Preparing Books on American Amphibia."

An early draft of the manuscript was nearing completion and the prospects for publication looked favorable in 1931. In a letter to Dr. Adams dated 27 March 1931 Bishop wrote,

> "The enclosure gives a brief outline of the items I have been covering in my account of the salamanders of New York. What is the news regarding the printing bill? I sincerely hope that it goes through and that the money will become available."

Further correspondences between the two men revealed that funds for printing could not be secured through the Museum or the University of Rochester. The Board of Regents, which appropriates the funds for the State Education Department, appears to have been reluctant to fund this project. This could be due to the fact that Bishop pursued "investigations in fields that may be regarded by some as having little economic importance" (Bishop 1928). This would not have been a unique mindset during that period. A few years earlier Bishop had corresponded with publisher G.P. Putnam about the prospects of publishing a field guide of salamanders. On 19 May 1927 Putnam wrote, "We here feel that a Field Book of Salamanders alone is likely not to have sufficiently wide appeal to warrant the rather heavy publishing investment."

In late 1931 Adams wrote, "there is a new prospect that looks hopeful" which did not materialize. In December of 1932, yet another attempt to gain appropriation of the funds failed. At this point the Great Depression was at its peak and the prospect of funds for publication was bleak.

While the New York State Archives does not contain any correspondences between Bishop and Adams in 1936, it was during that summer that Bishop wrote the text for *The Salamanders of New York* (B. B. Flory, pers. comm.). The fight to secure the funds to publish it continued until 1941. The final product was compromised because the color plates that Bishop had spent nearly 20 years collecting, and for which the University of Rochester had contributed $500, were photographed (i.e., black and white reproduction) to reduce the printing cost. Bishop's frustration over this was not lost on his friend and colleague Karl P. Schmidt. In review he wrote, "Those of Dr. Bishop's friends and colleagues who have seen the superb water-color paintings of the salamanders of eastern North America accumulated under his supervision over many years will have felt some regret at the appearance of his "Salamanders of New York" without color illustrations" (Schmidt 1943).

Bishop had established himself as a leading authority on salamanders by the time he began vocalizing his desires to finish *The*

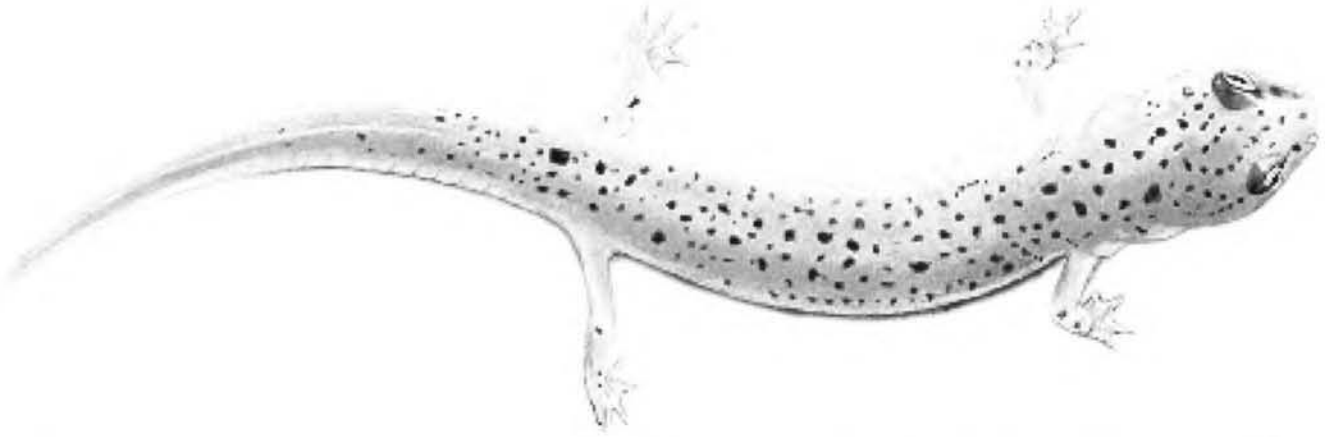

FIG. 1. Black-and-white reproduction of a watercolor depicting a larval *Pseudotriton ruber* (NYSM 3086) collected 10 June 1922 by S.C. Bishop in Albany County, New York, USA. The drawing (NYSM 940), by G. S. Barkentin, was prepared under the supervision of Bishop during fieldwork for *The Salamanders of New York*. It was not included in the monograph and is previously unpublished. To view the original watercolor and for more information on S.C. Bishop visit www.nysm.nysed.gov/biology/salamander/index.html.

Salamanders of New York in 1927, yet his knowledge of so many of the species was incomplete. It is interesting to consider what the document would have been if it had been published at Bishop's behest. The published bulletin contained 54 citations for works published after 1928. On the prospects of earlier publication, Bishop wrote to Adams on 30 November 1931, "This account should make a bulletin of about 200 pages." The bulletin, as it was printed in 1941, consists of 365 pages, a substantial increase from the estimate given by Bishop a decade earlier.

The species accounts given by Bishop (1927a) in *The Amphibians and Reptiles of Allegany State Park* provide a glimpse of his knowledge at the time he was pressing for completion of the larger work. Concerning the hellbender, Bishop wrote, "In New York State it is entirely confined to the Allegany river (sic) and a few of the larger tributaries except where introduced" (Bishop 1927a). By 1941 Bishop had changed his account to, "The distribution as at present known, may be summarized as follows: The Susquehanna and tributaries in New York and Pennsylvania; the Ohio river (sic) and tributaries including the Allegany in western New York" (Bishop 1941). He even goes so far as to correct the work of Stejneger and Barbour (1933), which failed to mention the Susquehanna populations. Based on Bishop's correspondences it is apparent that his views on the distribution of *Cryptobranchus* changed at the end of 1927. In a letter to Henry Fowler at The Academy of Natural Sciences, dated 30 December 1927, Bishop asked,

> "Can you tell me whether the Hellbender, *Cryptobranchus* is found in the Delaware River? I have records of the animal from the Susquehanna river (sic) both in Pennsylvania and New York, and have wondered if it were also introduced there. Baird reported it in 1850 and it is now so widely distributed in various tributaries of the river, it is perhaps native to the stream."

The record from the Susquehanna in New York was based on a recent correspondence with the Supervising Principal of Sidney Schools. In a letter to him dated 10 Januaury 1928, Bishop writes:

> "The Hellbender came through in fine condition this afternoon...so far as I know, is the first specimen recorded from the Susquehanna in New York...and has, undoubtedly been known to fisherman and others in New York; but records have not come to my attention."
>
> "Until now I have been going to the Allegany State Park to study the Hellbender. I now propose to have a look at the Susquehanna."

This specimen is not known to exist in any institutional collection. The first vouchered specimen from the tributaries of the Susquehanna in New York was collected on 11 May 1928 (NYSM 2732). The majority of specimens cited by Bishop (1941) from the Susquehanna were not collected until 1935.

At the time that Bishop (1927d) wrote the Report of the Zoologist, pressing to finish *The Salamanders of New York*, Wehrle's salamander (*Plethodon wehrlei*) had not been added to the herpetofauna of the State. It was late July of that year that Dr. R. E. Coker discovered their presence in Allegany State Park (NYSM 2653–2655) (Bishop 1927a). While the seven pages devoted to *P. wehrlei* is the shortest species account in *The Salamanders of New York*; it would have been even shorter had the publication been completed earlier.

The two species of *Desmognathus* also seemed to be of particular interest to Bishop during the early 1930's. In 1933 he published on the nests and young of *D. ochrophaeus* (Bishop and Crisp 1933). His personal collection, numbering more than 1000 individuals of both species (FMNH collection), was accumulated from numerous locations in western New York. Much of the data used by Bishop (1941) for the accounts of *D. ochrophaeus* are from fieldwork conducted during the 1930's.

By 1939, Bishop's health was failing due to stress-related illnesses. While it can only be speculated whether the decade-long struggle to see his work completed contributed to his failing health, it is known that if the timing of the publication of the bulletin had progressed according to Bishop's wishes, it quite possibly would not have had the impact on the discipline of herpetology that it has enjoyed. The additional time allowed him to expand his knowledge for the accounts of many of the species.

Bishop's work is a tribute to decades of persistence and perseverance by a strong-willed individual with a vision. Three popular publications on North American salamanders in print today are indebted to the precision of Bishop's accounts. It provided the basis for *The Handbook of Salamanders* (Bishop 1943), which remained the only composite work on North American salamanders for 55 years. *The Salamanders of Ohio* (Pfingsten and Downs 1989) was influenced heavily by Bishop's work. The recently completed *Salamanders of the United States and Canada* (Petranka 1998) relies on Bishop's descriptions of reproductive biology and ontogeny for species native to New York. Petranka's thorough review of each species has indirectly renewed focus on the extent of Bishop's work, placing it alongside subsequent salamander studies for comparison. It is now apparent that no other researcher has compiled as much information on egg clutches for the secretive red salamander (*Pseudotriton ruber*) as Bishop. Likewise, Bishop's accounts of the reproductive biology of the hellbender (*Cryptobranchus alleganiensis*) and four-toed salamander (*Hemidactylium scutatum*) are as complete as any published, while his earlier publications on the mudpuppy (*Necturus maculosus*) enabled him to write one of the most detailed original accounts of this species (Bishop 1926, 1932).

Acknowledgments.—I thank Kraig Adler, Robert Daniels of the NYSM, and Beth B. Flory (Bishop's daughter) for their assistance in researching this paper. Kraig Adler, Robert Daniels, and Kimberley Corwin Hunsinger reviewed drafts of this manuscript. This is Contribution number 796 of the New York State Museum and Science Service.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send three copies of manuscripts, double-spaced, directly to the appropriate section coeditor (addresses on inside front cover): J. Brian Hauge (lizards, amphisbaenians, crocodilians, *Sphenodon*); Charles W. Painter (amphibians); or Paul A. Stone (snakes, turtles). Authors are requested to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a text-only version of the file.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins (1997. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 4th ed., Herp. Circ. 25:1–40; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

DESMOGNATHUS IMITATOR (Imitator Salamander). **REPRODUCTION**. Eggs of many *Desmognathus* species are commonly deposited on the underside of rocks, in stream leaf litter, and in muddy seeps. Although there are two reports of eggs that were presumed to be those of *Desmognathus imitator*, neither was confirmed by identification of brooding females (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.).

We found six *D. imitator* clutches on 30 June 1998 in Swain Co., North Carolina, USA, at ca. 1600 m elevation (35°36'20"N, 83°26'56"W). The clutches were found within a seep in saturated soil and eggs were in early developmental stages. We observed one red-cheeked *Desmognathus* (40 mm TL) with her body in direct contact with a clutch, and saw other red-cheeked *Desmognathus* within 10 cm of clutches when we overturned rocks, confirming that the eggs were those of *D. imitator*. Eggs were cream colored and attached in a monolayer to the underside of flat rocks that were embedded in the soil, although one clutch had a small number of eggs arranged in a bilayer. Two of the clutches were deposited within 22 cm of each other but were on separate rocks. Means and ranges (in parentheses) for clutch parameters for five nests are: clutch size 19 (13–24) eggs; clutch length 19 (9–27)

mm; clutch width 10.4 (6–17) mm; and egg diameter 3.5 (3.0–4.0) mm (N = 55 eggs). Two clutches illustrated by Petranka (1998) are from the same site and contained 23 and 30 eggs.

The lack of information about the breeding and nesting habits of *D. imitator* is likely due to their small range and secretive nesting in subsurface retreats.

Our observations suggest that females nest in late spring and early summer and guard their eggs, presumably through hatching. The mode of egg deposition is more similar to that of *D. monticola* than to other members of the *D. ochrophaeus* complex.

SMITH**, Department of Biology, High Point University, University Station, High Point, North Carolina 27262, USA, **ELIZABETH A. DOMINGUE**, 320 Laurel Valley Road, Townsend, Tennessee 37882, USA, and **JAMES W. PETRANKA**, Department of Biology, University of North Carolina at Asheville, Asheville, North Carolina 28804, USA.

PSEUDOTRITON RUBER RUBER (Northern Red Salamander). **ALBINISM**. Several plethodontid species have been documented as having some degree of albinism in North America, many of which are listed by Palmer and Braswell (1980. Brimleyana 3:49–52) and Dyrkacz (1981. SSAR Herpetol. Circ. 11:131 pp.). However, this is the first documented occurrence of albinism for *Pseudotriton r. ruber* and for the genus *Pseudotriton.*

On 18 March 1998 an albinistic *Pseudotriton r. ruber* (85 mm SVL, 146 mm total length, 16 costal grooves) was collected at the Radford Army Ammunition Plant, New River Facility, Pulaski County, Virginia, USA (Fig. 1). Dorsal pigmentation was pale orange with pinkish-white spots on the head, trunk, and tail regions. The ventral integument was similar in color to the venter of a normally pigmented individual also collected at the site. The toe tips were white. Some dark pigment was present and scattered across the entire dorsum in small flecks (indicating partial melanin production), and the eyes were pinkish-white and appeared red when viewed with a light beam. The overall coloration of this individual is defined by Dyrkacz (*op. cit.*) as partially albinistic with xanthophores and erythrophores present. The specimen was photographed and released after being held in captivity for two weeks. Color slides were deposited in the University of Kansas Natural History Museum (KU CT 11720–21).

FIG. 1. Albinistic *Pseudotriton r. ruber* from Virginia.

ANURA

BUFO AMERICANUS (American Toad). **ENDOPARASITE**. New host records reveal previously unstudied host-parasite relationships that may be important to parasite-models of sexual selection (Hamilton and Zuk 1982. Science 218:384–387) and amphibian deformities (Johnson et al. 1999. Science 284:802–804). Although *Clinostomum marginatum* has been studied in *Hyla chrysoscelis* (Hausfater et al. 1990. Amer. Zool. 30:299–311), there are no records of *C. marginatum* metacercariae in *Bufo americanus*. Herein we report the presence of this digenean parasite encysted in adult *B. americanus*. During the 1997 breeding season (25 March–8 April), one of us (JMH) noted the encysted metacercariae in 17 of 69 (24.6%) adult *B. americanus* at a farm pond (ca. 0.04 ha) in Oklahoma County, Oklahoma, USA (35°41'13"N, 97°14'55"W). We collected one female and one male toad that were infected with encysted metacercariae on 19 September 1997 and 30 April 1998 to identify the parasite and describe the infection. We inspected the subcutaneous tissues, mesenteries, and internal organs for encysted parasites and removed 75 metacercariae from each toad. Cysts from which metacercariae did not escape were placed in amphibian Ringer's solution and were pulled apart to free the metacercariae. Flukes were fixed in CAFA (30% chloroform [v/v], 50% alcohol [v/v], 10% formalin [v/v] and 10% acetic acid [v/v]) and stained. Microscopic examination revealed the metacercaria to be the digenean fluke *C. marginatum* (C. R. Bursey, pers. comm.). Encysted and liberated *C. marginatum* were found in the abdominal subcutaneous tissues, mesenteries of the small and large intestine, pericardium, skeletal muscle, and in the brain immediately posterior to the eyes. No metacercariae were found inside viscera. Toad and parasite specimens were deposited into the Herpetology Collection of the University of Central Oklahoma (UCO 380, 712). The first intermediate host (*Helisoma* sp.) and potential definitive hosts (*Butorides striatus*, *Nerodia rhombifer*) have been observed at this pond (JMH). The convergence of hosts at the pond ensures a complete life cycle for this fluke as well as infestation of new *B. americanus* cohorts.

We thank Charles R. Bursey and Stephen R. Goldberg for the identification of metacercariae of this parasite and Marvin Mays for his assistance in the recovery and preliminary identification of this parasite.

BUFO OCCIDENTALIS (Pine Toad). **FECUNDITY**. Anurans are well known for their ability to produce large clutches of eggs (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Co., New York. 670 pp.), with the largest clutch recorded from a *Rana catesbeiana* that laid 47,840 eggs (McAuliffe 1978. Nebraska Game and Parks Report, Lincoln). North Ameri-

can bufonids also noted for laying large clutches include *Bufo cognatus* (45,054 eggs; Krupa 1994. J. Herpetol. 28:217–224), *B. americanus* (13,452 eggs; Kruse 1981. Herpetologica 37:228–233), and *B. woodhousii* (28,493 eggs; Krupa 1995. Herpetol. Rev. 26:142–143).

On 27 Oct 1998 at ca. 2030 h we collected a female (LOL-031; 86 mm SUL) and male (LOL-032; 81.5 mm SUL) *B. occidentalis* in amplexus at Zapotitlán de las Salinas, Puebla, México (18°07'18"N; 97°19'24"W) at 1420 m in deciduous tropical dry forest. Specimens were collected and taken to the Laboratoria de Ecología de la UBIPRO where amplexus continued until ca. 0400 h the next day. During that time, the female laid two clutches of eggs. The first clutch was laid at ca. 2030 h and contained 8380 eggs (mass 187.8 g); the second was laid ca. 0400 h and contained 2352 eggs (mass 59.5 g). Total clutch size and mass was 10,732 eggs and 247.4 g. This is the first report of large clutch size in Mexican bufonids.

We thank G. Woolrich, J. González, and V. Mata for their support. Funding was provided by the Dirección General de Apoyo al Personal Académico (DGAPA-UNAM), Project No. IN208398.

GASTROPHRYNE OLIVACEA (Narrow-mouthed Toad). **VOCALIZATION.** Territorial calls in anurans are presumed to be used in agonistic interactions between males in close proximity (Duellman and Trueb 1986. Biology of Amphibians. McGraw Hill, New York. 577 pp.). There are no reports of territorial calls in the microhylid *Gastrophyrne olivacea*. Here I report *G. olivacea* in close proximity producing a distinctive call that was not the breeding advertisement call (Conant and Collins. 1991. Reptiles and Amphibians of Eastern and Central North America. Third edition. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). Based on circumstances and associated behavior, I interpret this call as a territorial call.

On 18 June 1999 at 1530 h I heard 3 *G. olivacea* calling from a 1 m^2 area in a dry wash in Big Bend National Park, Texas, USA (UTM 680936e, 3262586n, Zone 13, Brewster Co., Texas, T_A = 33.0°C). The calls were 0.5 sec in duration and resembled a short, low-pitched nasal buzz. When one male called, the other two responded immediately. I confirmed species identification by capturing two males that were within 0.09 m of each other. One was underneath a clump of grass and the other was from a crack in the dirt bank. I did not capture the third individual calling from a rock crevice 0.8 m away from the others. There were 45 sec to 2 min of silence between calls. On 19 June 1999 at 2055 h I heard similar calls from five *G. olivacea*, within 8 m of one each other, located beneath four separate clumps of grass 20 m from a stock tank. Calls were separated by 10–40 sec. There were 2–5 individual responses for each call made.

These two observations document the existence of a call other than the typical advertisement call of *G. olivacea*. The calls were not associated with a breeding chorus and elicited strong response from nearby males. I suggest this call is agonistic between males and functions to establish territories. While breeding choruses of *G. olivacea* occur after heavy summer rains (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, New Mexico. 431 pp.), it may be beneficial to amphibians living in stochastic environments to establish territories prior to the presence of water when rainfall events can create breeding environments in a matter of minutes.

I thank Lee A. Fitzgerald, Lily Ryder, and Ryan Nelson for their helpful comments and positive criticism. Raymond Skiles and Vidal Davila at Big Bend National Park provided tremendous logistical support. This study is part of DISPro (the Demonstration Intensive Site Program), a joint index site and ecological research program funded by the U.S. Environmental Protection Agency and National Park Service.

HYLA ALVARENGAI (NCN). **DEATH FEIGNING AND SIZE AT MATURITY**. *Hyla alvarengai* is a saxicolous, large-bodied hylid frog known only from parts of the Serra do Espingaço range, in the Brazilian state of Minas Gerais (Duellman 1993. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 21:1–372). Little is known about its biology and natural history, with most available information in Sazima and Bokermann (1977. Rev. Bras. Biol. 37:413–417) who discuss antipredator tactics including crypsis, leaping, seeking refuge in crevices, cutaneous exudation of a sticky substance, and the use of prepollical spines as defensive weapons by the males. Here we describe a new antipredator behavior for the species.

On 28 November 1998, during field collection at Sopa, Diamantina Municipality (18°12'S; 43°42'W), Minas Gerais, Brazil, we found an adult female (eggs could be seen through the skin) *H. alvarengai* (69 mm SUL) resting in the narrow space between two large boulders. At our first attempt to capture it, the frog leapt high and landed on a boulder where it remained still and was readily caught. Immediately after being captured, the frog thrust its front limbs upward to its eyes and remained motionless, with eyelids half-closed and the pollex of each hand below the corresponding eye and the remaining fingers above it. We then turned the frog belly-up and it remained in that position with hind legs tucked under the body for several seconds while photographs were taken, until it suddenly moved and appeared lively again. It then attempted to escape and was restrained, whereupon it again feigned death, this time with the front legs tucked under the body. It remained in that position for an even longer period, and was finally placed into a plastic bag while still feigning death. The specimen was fixed in 10% formalin and deposited at the Museu Nacional do Rio de Janeiro (MNRJ 23471). This specimen was smaller than the smallest of five mature female *H. alvarengai* (78 mm SUL) examined by Sazima and Bokermann (*op. cit.*) and is the smallest mature female of this species reported.

We thank Marcelo F. Nápoli and José P. Pombal Jr. for identification of the frog.

NECTOPHRYNOIDES VIVIPARUS (NCN). **DIET**. While conducting herpetological research in the Uzungwa Mountains rainforest, (Tanzania, Iringa Region, Kihanga Valley 1780 m, 08°22'24"S, 35°58'43"E), we collected data on the diet of the ovoviviparous toad *Nectophrynoides viviparus* (Lamotte and Xavier 1972. Bull. Soc. Zool. Fr. 97:413–428). To our knowledge, these data are the first published report of food habits of this species, which is endemic to central and southwestern Tanzania (Perret 1972. Ann. Fac. Sci. Cameroun 11:93–119).

During the rainy season of January 1999, we stomach flushed 20 *N. viviparus* specimens: 8 adults (mean SVL = 46.59 mm; SD = 4.75, range 38.4–53.4 mm) and 12 juveniles (mean SVL = 28.63 mm; SD = 3.40, range 24.1–34.0 mm). During the day toads were found under rotten logs and in the leaf litter and at night on vegetation up to 1.5 m above ground. Specimens were stomach flushed (Fraser 1976. Ecology 57:238–251) and immediately released at the capture site (Table 1).

The mean number of prey items per stomach was 8.3 (SD = 15.3). The highest number (64 ants) was obtained from a 34 mm SVL juvenile. Prey length varied from 1.5 to 15 mm, and prey volume from 0.3 to 18 mm^3. Plant material consisted of leaf remains and seeds. Results indicate these toads are opportunistic feeders, and at least during the rainy season, ants are their most frequent prey.

TABLE 1. Food habits of *Nectophrynoides viviparus* from Kihanga Valley, Uzungwa Mountains, Tanzania.

PSEUDACRIS STRECKERI ILLINOENSIS (Illinois Chorus Frog). **FROST INJURIES**. The fossorial chorus frog, *Pseudacris streckeri illinoensis*, is limited to sandy habitats in Illinois (Smith 1961. Bull. Illinois Nat. Hist. Surv. 28:1–298). Sandy habitats may be the only areas where the frog can burrow deeply enough to escape freezing, which is fatal to the species (Packard et al. 1998. J. Herpetol. 32:437–440).

Pseudacris s. illinoensis is moderately proficient at burrowing (Axtell and Haskell 1977. Nat. Hist. Misc. 202:1–8; Brown et al. 1972. Herpetologica 28:325–328; Tucker et al. 1995. Herpetol. Rev. 26:32–33). However, the actual depth that *P. s. illinoensis* burrows in winter is unknown. Nonetheless, unusually severe winters may affect this frog. For instance, the winter of 1995–1996 was unusually severe with one period during February where temperatures remained below –15° C for a week. Moreover, snow cover was absent during this period. Although I observed no direct evidence of mortality, 67% of 41 specimens caught at a study site in Madison County, Illinois, USA during spring 1996 had what I interpret to be frost injuries (Fig. 1). These injuries were similar among the 28 frogs observed. All frogs had areas of discolored skin located on the dorsal side above the illial prominences (Fig. 1). Most frogs also had discrete discolored areas at the ankles and knees (Fig. 1). Some frogs such as the one depicted in Fig. 1 had blistered skin on the ankles or knees.

I suggest that these injuries occurred when the sand froze to a depth deep enough to include the roofs of burrows containing overwintering frogs. In each case injuries occurred to portions of the frog most likely to be in contact with the roof of the burrow. The natural occurrence of such injuries following a particularly severe winter indicates the importance of substrates that allow deep burrowing by *P. s. illinoensis* in northern regions (Packard et al., *op. cit.*).

No frogs were found with suspected frost injuries to the abdomen or other ventral surfaces. These parts of the frog might also be expected to show signs of injuries given the small diameter of the frogs' burrows (Tucker et al., *op. cit.*). However, had the burrows become completely frozen, the frogs should have died given their intolerance of subfreezing temperatures (Packard et al., *op. cit.*) and would not be recovered. The lesions I report remain visible on frogs marked in spring 1996 and recaptured in spring of 1999. It seems unlikely that some sort of bacterial or fungal infection would be as persistent. Moreover, these naturally occurring lesions closely resemble those on other anurans made by freeze-branding (Daugherty 1976. Copeia 1976:836–838).

FIG. 1. Possible frost injuries to a female (42 mm SVL) Illinois chorus frog (*Pseudacris streckeri illinoensis*) suggested by the discolored areas above the illial prominences and blistering of the skin on the frog's right knee.

Gary L. Paukstis made the photograph of the frog and Gary C. Packard provided the print. Research on chorus frogs in Madison County, Illinois is supported by a grant from the Illinois Department of Transportation.

Submitted by **JOHN K. TUCKER**, Great Rivers Field Station, Illinois Natural History Survey, 4134 Alby Street, Alton, Illinois 62002, USA.

RANA CAPITO (Gopher Frog). **PREDATION**. Aresco and Reed (1998. Herpetol. Rev. 29:40) reported predation of larval *Rana capito* in southern Alabama by the banded water snake, *Nerodia fasciata*. Here, I report predation of adult *R. capito* by the same species at Holley Pond, Eglin Air Force Base, Okaloosa County, Florida, USA (30°33'56"N, 86°45'04"W). At ca. 2100 h on 3 October 1994, I collected an adult *N. fasciata*, ca. 100 cm TL, swimming on the water surface at Holley Pond. Forced regurgitation of a large food bolus in its mid-section yielded an adult *R. capito*. The frog was still alive, though lightly bleeding through several minor cuts and from the tympana. The specimen later died and was deposited in the Florida Museum of Natural History collection (UF 103332).

The following year on 3 May 1995, I collected an ca. 80 cm *N. fasciata* from the same pond and successfully forced regurgitation of its gut contents. Included among unidentifiable material was the hind limb of *R. capito*.

These observations, along with those of Aresco and Reed (*op. cit.*), suggest that *N. fasciata* may be an important predator of both larval and adult *R. capito*.

These observations were made in conjunction with a study of rare amphibians conducted by the Florida Natural Areas Inventory and supported by the U.S. Department of Defense Legacy Program.

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA; e-mail: john_jensen@mail.dnr.state.ga.us.

RANA SPHENOCEPHALA (Southern Leopard Frog). **SUBTERRANEAN VOCALIZATION**. Although male *Rana sphenocephala* typically call while floating at the water surface or from cryptic locations among inundated vegetation, they occasionally call while submerged (Wright 1932. Life Histories of the Frogs of Okefinokee Swamp, Georgia. MacMillan Co., New York. 497 pp). Herein I report a *R. sphenocephala* calling while submerged underground.

At 1420 h on 7 February 1999, I heard a muted call of *R. sphenocephala* adjacent to a roadside ditch in Union County, Illinois, USA (T12S R3W Sec 12). After taking two steps in the direction of the call, I pinpointed the call directly beneath me. Parting the low grass, I uncovered a 6 cm diameter crawfish burrow from which the call was still emanating. The frog was not visible at the water surface, indicating that it was calling while submerged in the burrow. I dug out two adult male and one gravid adult female *R. sphenocephala* from 0.7 m below the soil surface. The frogs likely retreated to that depth as I excavated the burrow. Both males had flaccid vocal sacs indicating they had been calling. The water within the burrow was 10°C and the air was 11°C. Subterranean calling by *R. sphenocephala* may provide protection from predators that locate frogs aurally but are unable to follow frogs into their underground retreat or extricate them from it.

Submitted by **JOHN G. PALIS**, P.O. Box 387, Jonesboro, Illinois 62952, USA.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). **PREDATION**. Because *Scaphiopus holbrookii* is generally fossorial, observations of post-metamorphic predation are infrequent. Herein I report one probable and two confirmed predators of post-metamorphic *S. holbrookii* that, to my knowledge, have not previously been reported.

On 30 March 1993, while observing a *S. holbrookii* breeding chorus in Oklaoosa County, Florida, USA (T1N R24W Sec 34), I observed an ca. 0.6 m TL *Nerodia fasciata* holding an adult male *S. holbrookii* at midbody. The snake was manipulating its jaws towards the spadefoot's head. I watched a ca. 0.9 m TL *N. fasciata* swallow an adult male *S. holbrookii* at this same site on 1 March 1994.

On 28 May 1996, I observed 10 European starlings (*Sturnus vulgaris*) foraging on a lawn adjacent to a *S. holbrookii* breeding site in Union County, Illinois, USA (T12S R1W Sec 19). With the aid of binoculars I determined that the starlings captured and consumed at least two *S. holbrookii* metamorphs that had emerged from the pond six days earlier. The clearest observation was that of an immature starling taking a metamorph from the beak of an adult bird.

On 31 May 1996, I observed a common grackle (*Quiscalus quiscula*) on the lawn with an object in its beak the size on a *S. holbrookii* metamorph. I walked slowly towards the grackle which dropped the object and flew away. I found a metamorph on the ground where the bird had been, but I do not know if the metamorph was the object the bird dropped or if it coincidentally happened to be at that spot. However, given that grackles prey on small frogs (Terres 1991. The Audubon Society Encyclopedia of North American Birds. Wings Books. Avenel, New Jersey. 1109 pp.), it is likely that the bird was feeding on *S. holbrookii* metamorphs.

Observations in Florida were made while conducting a gopher frog survey of Eglin Air Force Base, financially supported by the U.S. Dept. of Defense Legacy Resource Management Program through contract with The Nature Conservancy. I thank Ronald Brandon for access to his library.

TESTUDINES

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **FISHING NET INGESTION**. The ingestion of marine debris such as plastic bags by *Demochelys coriacea* has been documented (Mrosovsky 1981. Marine Turtle Newsl. 17:5–7; Fritts 1982. Herpetol. Rev. 13:72–73). Frazier (1980. *In* Edge [ed.], Proceedings of the Second Symposium on Coastal and Ocean Management, Vol. III., pp. 2395–2411) noted that plastics and other marine debris are indigestible and may cause intestinal problems that lead to death. Marine debris such as plastics and pieces of fishing net may resemble jellyfish, the main prey item of *D. coriacea*, in both texture and color.

Here, we report a nesting *D. coriacea* that partially ingested a nylon fishing net. On 5 June 1998, a female *D. coriacea* (155 cm CCL) nesting on North Vogelkop Coast, Irian Jaya, Indonesia, was found to have two meters of nylon fishing net protruding from her mouth (Fig. 1). One end of the net was lodged within the digestive tract of the turtle, and the other end trailed out the left side of the turtle's mouth, where it had worn a fibrous groove at the joint of the mandibles. The net had a large cluster of gooseneck barnacles (*Lepas* spp., 0.5–2.0 cm length) attached. Two strands of the net (ca. 1 m) were pulled from the turtle's mouth; the distal ends of the net were covered with blood. Further attempts to extract the net were discontinued as it was obviously damaging the turtle internally. Nesting was successful although movements were hampered as the net wrapped around the fore-flippers of the turtle as she covered her nest.

FIG. 1. Nesting female *Dermochelys coriacea* with nylon fishing net protruding from mouth.

The impact of modern longline, drift, and set gill-net fishing on sea turtles is of increasing concern for both fisheries managers and sea turtle conservationists. Interactions between fishing gear and sea turtles are more frequent due to modernization of the fleet: vessels with greater operating distances, navigational aids, and more effective synthetic nets. Sea turtles that spend much of their lives in the open sea such as *Carreta carreta* and *D. coriacea* are at risk of encountering these fisheries. Nets that have broken free from fishing boats may attract large predators like *D. coriacea* who mistake them for prey.

TERRAPENE CAROLINA CAROLINA (Eastern Box Turtle). **INTRASPECIFIC COMBAT**. Apparent male-male combat has been observed in many turtles, but in some species it is debated whether apparently combative behavior represents aggression. Stickel (1989. J. Herpetol. 23:40–44) reported behavior between *Terrapene carolina* males analogous to male-female courtship behavior (Evans 1953. Herpetologica 9:189–192), and concluded that apparently aggressive male-male behavior does not represent aggression. I report here an observation of similar behavior between two male *T. carolina* that differs significantly from male-female courtship.

At 0945 h on 10 August 1995 (clear sky, no rain for at least two days) between U.S. Highways 11 and 129 in Jones Co., Georgia, USA, I encountered two *T. carolina*, one in pursuit of the other in a recently clear-cut pine forest. After all observations were made, I determined that both turtles were male. Neither turtle was measured, but the larger (X) had 18 distinct growth rings on the carapacial scutes, while the smaller (Y) had a pitted but otherwise smooth plastron and a pitted carapace with 14 growth rings.

The two stopped and began alternating sessions of head-on ramming. One turtle would initiate a series of 6–10 rams, with the other meeting each blow by either retreating into the shell or remaining within the shell from previous blows. The other turtle would then initiate a series of rammings; the two alternated in this manner for at least 10 min. Each turtle also bit the other repeatedly; the ramming/biting turtle lunged with mouth open at its opponent. Turtle X consistently landed bites on or near turtle Y's beak, at one time locking jaws. Turtle Y consistently bit its opponent on the rostral carapacial marginals.

After leaving for 10 min. to retrieve a camera, I returned to find turtle X mounted from the rear on Y's carapace; Y's shell was tightly closed. They remained in this position without apparent movement for 15 min., after which Y began to crawl away with X in pursuit. Both traveled apparently as fast as possible for about 3–4 m, with X in pursuit and repeatedly biting Y on the caudal marginals. When Y stopped and retreated into its shell, X again mounted Y for several min. (Fig. 1), after which X again chased Y for about 2 m. Then, X again mounted Y for several min. Y then quickly moved into brush about 10 m away without X in pursuit. X remained stationary for 25–30 min. after which he turned in the

FIG. 1. Male *Terrapene carolina* (X) mounted from rear on another male *T. carolina* (Y). No attempted copulatory behavior was observed. Y's plastron is tightly closed.

direction opposite Y's retreat and quickly crossed a logging road (in the direction from which both originally came).

Apparently aggressive behavior between males has been observed in several turtles including *Kinosternon baurii* (Carr 1940. Univ. Florida Biol. Sci. Ser. 3:1–118), *Clemmys guttata* (Ernst and Barbour 1972. Turtles of the United States and Canada. University of Kentucky Press, Lexington, Kentucky. 578 pp.), *Gopherus agassizii* (Ernst and Barbour, *op. cit.*), *G. berlandieri* (Weaver 1970. Bull. Florida St. Mus. 15:1–43), and *G. polyphemus* (Weaver, *op.cit.*). Weaver's observations on captive *Gopherus* indicate that male-male aggression is stereotyped and significantly different from male-female courtship. Conversely, male *T. ornata* mounted by other males exhibited snapping behavior analogous to that sometimes exhibited by mounted females (Brumwell 1940. Trans. Kansas Acad. Sci. 43:391). The behavior reported here is similar to initial phases of male-female courtship in *T. carolina*, but differs in that the pursued male never submitted to the pursuer, and in that the two turtles engaged in chasing behavior. More importantly, this observation differs from all reported observations of male-male *T. carolina* encounters in that the two individuals reported here alternated the initiation of sessions ramming and biting each other. Therefore, these observations indicate that aggressive encounters do occur between male *T. carolina*.

SERPENTES

BOIGA IRREGULARIS (Brown Tree Snake)**. SEASONAL ACTIVITY.** The introduced population of *Boiga irregularis* on Guam, Mariana Islands, is known to exhibit a seasonal activity pattern. Three lines of evidence support seasonal activity patterns of *B. irregularis* on Guam: power outages resulting from arboreal activity, envenomation reports of humans from medical facilities, and sighting rates from nocturnal surveys (Rodda et al. 1999. *In* Rodda et al. [eds.], Problem Snake Management: The Habu and the Brown Treesnake, pp. 44–80. Cornell University Press, Ithaca, New York). These data suggested that *B. irregularis* exhibit greater levels of activity at the beginning and during the rainy season (June–December). In the native range, Bull and Whittier (1996. Mem. Queensland Mus. 39:483–486) tabulated collecting dates of museum specimens from eastern Australia and surmised that these were also reflective of unimodal seasonal activity patterns. Bull and Whittier (*op. cit.*) concluded that heightened activity of *B. irregularis* was tied to increasing temperature and rainfall.

Highway mortality has been used as a measure of seasonal activity in temperate snakes (Gibbons and Semlitsch 1987. *In* Seigel, et al. (eds.), Snakes: Ecology and Evolutionary Biology, pp. 396–421. McGraw Hill, Inc., New York.). Between October 1988 and September 1990, a 20.4 km section of highway on Guam was driven daily and 184 DOR *B. irregularis* were collected (Fig. 1). DOR totals plotted by month against mean monthly rainfall (Anonymous 1990. NOAA Natl. Clim. Data Center, Asheville, North Carolina, 8 pp.) indicated an activity pattern similar to that reported by Rodda et al. (*op. cit.*) and Bull and Whittier (*op. cit.*). More DOR *B. irregularis* were encountered during the rainy season than during the dry season (G_{adj} = 10.596, 0.005>p>0.001).

FIG. 2. Male *Terrapene carolina* (X) in pursuit of male Y between alternating bouts of ramming and biting.

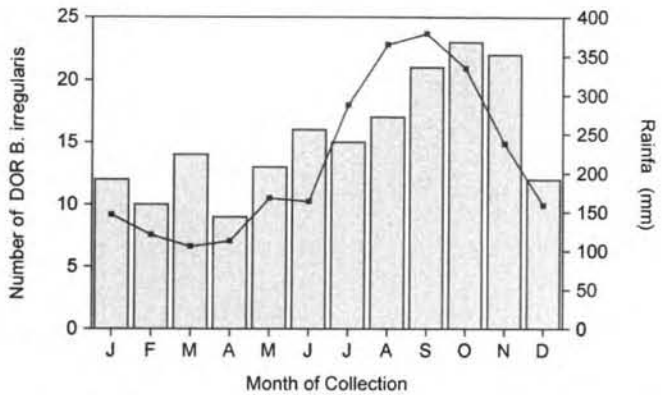

FIG. 1. DOR *Boiga irregularis* recorded between October 1988 and October 1990 along a 20.4 km section of highway on Guam, Mariana Islands. Columns represent total observations of snakes by month. Squares connected by lines represent mean monthly rainfall totals.

The data verify the activity pattern reported by Rodda et al. (*op. cit.*), support an activity pattern hypothesized by Gibbons and Semlitsch (*op. cit.*) for tropical snakes in seasonal environments, and suggest that seasonal activity patterns can be discerned for some species of tropical snakes using highway mortality statistics.

BOTHROPS CAMPBELLI (Campbell's Lancehead). **DIET** and **REPRODUCTION**. The poorly known pitviper *Bothrops campbelli* Freire 1991 inhabits lower montane wet forests and cloud forests along the western versant of the Cordillera Occidental of the Andes in Colombia and Ecuador (Kuch 1997. Bull. Zool. Nomenclature 54:245–249). Here we provide the first data on diet and reproduction in this species. A large female *B. campbelli* (SVL 920 mm, tail length 137 mm), collected in Huagal, Cantón Pallatanga, Province of Chimborazo, Ecuador (1500 m elevation; ca. 79°02'W, 2°10'S) on 29 April 1992 by A. Lema, contained a partly digested, rat-sized rodent. In addition, this snake contained 36 follicles measuring 10 mm in diameter, nine of 5–10 mm, and about 50 of 2–4 mm. The specimens are deposited in the herpetological collection of the Instituto Nacional de Higiene y Medicina Tropical, Guayaquil (INHMT 2622). The reproductive potential of this *B. campbelli* resembles that of a large *B. microphthalmus* (750 mm SVL), which contained 36 embryos (Kuch and Freire 1995. Herpetozoa 8:81–83). *Bothrops microphthalmus* is found in comparable habitat and altitude in the Amazonian versant of the Andes in Colombia, Ecuador, and Peru.

BOTHROPS NEUWIEDI PAULOENSIS (Jararaca Rabo-de-osso). **PREDATION**. Records of predation on neotropical snakes are scarce. Here we report predation on *Bothrops neuwiedi pauloensis* by the burrowing owl *Athene cunicularia* (Aves: Strigidae). The observation occurred on 7 September 1998 at 2020 h in Parque Nacional da Emas (18°06'S, 52°55'W, 760–880 m elev.), municipality of Mineiros, Goiás, Brazil. *Bothrops neuwiedi pauloensis* occurs in high densities in open habitats in the park. The predation occurred in a recently burned area of "campo limpo" (open grasslands). The snake (young male, 365 mm SVL, 65 mm tail length) was found decapitated on the ground, where the owl left it as we approached. The snake was still showing motor reflexes, indicating that it had just been attacked. A termite mound (1.6 m high), 7 m from the prey, was apparently used by the owl as a perch, similar to the hunting tactics described by Martins and Egler (1990. Rev. Bras. Biol. 50:579–584). There were many bird droppings on the ground near this hunting perch, indicating frequent use of the site by the predator. Snakes are uncommon prey items of *Athene cunicularia*, and no reports of predation on *B. neuwiedi* are available (Clark et al. 1997. J. Raptor Res. Report 9:145–170). The snake was deposited in the herpetological collection of the Instituto Butantan (IB 59909).

CROTALUS SCUTULATUS SCUTULATUS (Mojave Rattlesnake). **DEFENSIVE BEHAVIOR**. Neck spreading is a defensive display that previously has been reported in rattlesnakes only for *Crotalus scutulatus salvini* (Glenn and Lawler 1987. Herpetol. Rev. 18:15–16). An adult *C. s. scutulatus* ca. 1 m total length (TL) was AOR at 1700 h, 13 October 1996, on Hwy 54, 30 mi north of Van Horn, Culberson County, Texas, USA. A photograph of its defensive display showed the neck immediately posterior to the head to be spread laterally and the cervical spine to be straight and aligned with the head (Fig. 1). Based on an estimated SVL/TL proportion, this individual appears to be a male.

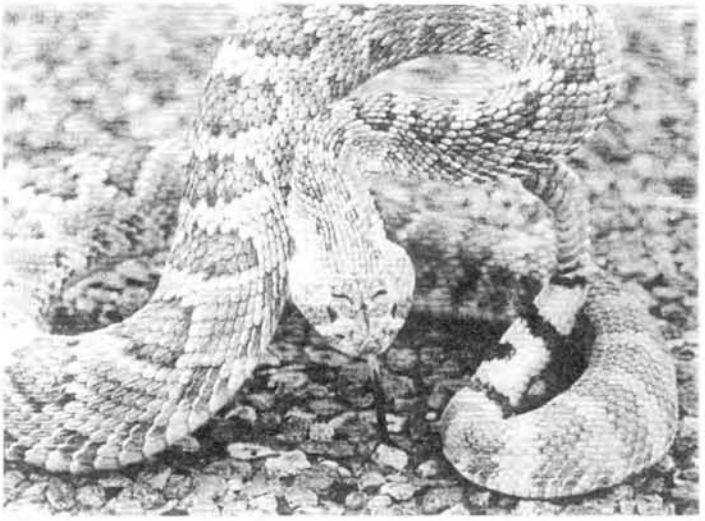

FIG. 1. Defensive display of *Crotalus s. scutulatus*, illustrating the neck spreading described in the text.

EUNECTES MURINUS (Green Anaconda). **CANNIBALISM**. One instance of cannibalism in the green anaconda (*Eunectes murinus*) has been reported in the literature (O'Shea 1994. Herpetol. Rev. 25:124). This observation involved a female eating a smaller conspecific of unknown sex. Here, we report three other cases of female anacondas eating conspecifics. These observations occurred during the breeding (dry) season in the Venezuelan llanos, Distrito Muñoz, Apure State (7°30'N, 69°18'W).

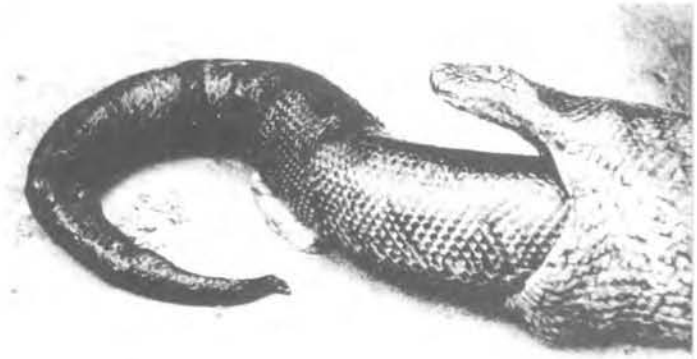

FIG. 1. Female anaconda regurgitating a male (note the hemipenis). Photograph courtesy of Tony Rattin.

The first observation involved a large female (434.7 cm total length [TL], 40 kg) that was caught 27 April 1995 next to a breeding aggregation (Rivas 1999. Life History of the Green Anaconda with Emphasis on its Reproductive Biology. Ph.D. dissertation. Univ. Tennessee, Knoxville. 269 pp.), but not participating in it. The snake had the engorged stomach that indicates a recent meal. After being put in a cage, she regurgitated a male anaconda (42 cm tail length, 283 cm estimated TL, 5.7 kg, Fig. 1). On 28 May 1996, at the end of the breeding season, we discovered another female constricting a medium-sized male (230 cm TL; 5 kg). The male was dead by the time we found it, and the female (370 cm estimated TL) managed to escape when we tried to capture her. Judging by the girth and overall condition of the snake, she was most likely breeding, and probably had just recently finished her mating activity. Lastly, on 18 March 1997 we collected a fecal sample that contained anaconda scales. The sample was from a female anaconda (300 cm TL, 14.8 kg) that was breeding that season.

All four records of cannibalism in green anacondas involve cannibalistic females, and the sex of the cannibalized individual has been male in the two instances in which sex could be determined. This asymmetry is probably a consequence of the strong sexual size dimorphism found in the species, with females much larger than males (Rivas, *op. cit.*). Green anacondas concentrate around the more permanent water sources during the dry season, and at this time breeding occurs (Rivas, *op. cit.*). Male anacondas looking for water and/or breeding females appear to be especially vulnerable to cannibalism by females. After mating, pregnant females do not eat for seven months (Rivas, *op. cit.*). It is possible that breeding females eat their mating partners in order to help them survive the long fast associated with pregnancy.

We thank The Wildlife Conservation Society and The National Geographic Society for funding this research, and COVEGAN for allowing us to work on their land. We also thank G. M. Burghardt for comments on the manuscript.

HELICOPS INFRATAENIATUS (NCN). **DIET**. *Helicops infrataeniatus* is a colubrid snake with aquatic habits, common in southern South America (Deiques and Cechin 1990. Acta Biol. Leopoldensia 12:313–326). Despite a lack of detailed information on the diet of this snake, it appears that its most frequent prey are fishes and frogs (Lema et al. 1983. Com. Mus. Ci. PUCRS. 26:41–121). We dissected 67 preserved *H. infrataeniatus* from Santa Maria, Rio Grande do Sul, Brazil (53°42'W, 29°43'S). Prey items in the esophagus and stomach were recorded. Of the 67 specimens, 14 (21%) contained food items that were recognizable to some taxonomic level. Twelve snakes contained fish scales and bones from the teleost families Characidae and Cichlidae. The other two snakes contained tadpoles of the frog *Phyllomedusa iheringii*; one of these snakes also contained bones of an adult *P. iheringii*. Tadpoles of *P. iheringii* have not previously been reported in the diet of *H. infrataeniatus*.

The specimens are deposited at Universidade Federal de Santa Maria (UFSM), Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul (MCP) and Museu de Ciências Naturais da Fundação Zoobotânica do Rio Grande do Sul (MCN). We thank Marcos Di-Bernardo (MCP) and Moema L. de Araújo (MCN) for permission to examine the snakes and José Francisco Pezzi da Silva and Paulo Cristiano Garcia for identifying the fish and tapdoles, respectively. The FAPERGS provided a grant to Aline Costa Feltrim (process # 94/60853.9).

Submitted by **ALINE COSTA FELTRIM** and **SONIA T. ZANINI CECHIN**, Departamento de Biologia, Setor de Zoologia, Universidade Federal de Santa Maria, Faixa de Camobi, KM 9, Santa Maria, Rio Grande do Sul, Brazil, CEP 97105-900 (e-mail [ACF]: afeltrim@zaz.com.br).

LEPTODEIRA BAKERI (Aruban Cat-Eyed Snake). **REPRODUCTION**. Although some information is available concerning reproduction of snakes of the genus *Leptodeira*, none has been published for *Leptodeira bakeri* (Ruthven 1936. Occas. Pap. Mus. Zool. Univ. Michigan 330:1–2; Duellman 1958. Bull. Am. Mus. of Nat. Hist. 114:5–152; Himmelstein 1980. Bull. New York Herpetol. Soc. 16:18–34; Fitch 1985. Misc. Publ. Univ. Kansas Mus. Nat. Hist. 76:1–76; Lee 1996. The Amphibians and Reptiles of the Yucatan Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.). On 1 August 1990, Toledo Zoo staff collected a pair of *Leptodeira bakeri* on Aruba. On 21 December 1992, the female produced a clutch of six eggs (mean ± SE mass = 3.6 ± 0.14 g). Eggs were incubated together at ca. 30°C in a small plastic container with several small holes punched in the top. Vermiculite and distilled water mixed at a 1:1 ratio by mass was used as an incubation substrate. One egg became rotten and was discarded on 2 February 1993. On 13 February 1993 the neonates slit their eggs. By the following day, all five of the neonates (139 ± 5.5 mm SVL, 2.6 ± 0.11 g mass) had emerged. The female weighed 72.0 g on 19 December, two days prior to oviposition, and 57.6 g on 21 December, immediately after oviposition. Total mass of the eggs was 21.7 g.

Submitted by **WILLIAM P. FLANAGAN III**, and **R. ANDREW ODUM**, Department of Herpetology, Toledo Zoological Society, 2700 Broadway, Toledo, Ohio 43609, USA (e-mail: herpers@toledozoo.org).

OPHEODRYS AESTIVUS (Rough Green Snake). **PREDATION.** On 9 July 1999, while conducting behavioral research on *Crotaphytus collaris*, we observed the posterior portion of a dead, hatchling *Opheodrys aestivus* hanging from the mouth of an adult female (94 mm SVL) *C. collaris*. The incident took place at Sooner Lake Dam, Pawnee Co., Oklahoma, USA. The lizard was noosed to confirm the identity of the prey. Examination of the visible portion of the snake suggested a total length of ca. 200 mm with ca. 98 mm hanging from the mouth. Upon release, the lizard completed its consumption of the snake within 2 min. Neither animal was collected.

To our knowledge this is the first report of lizard predation on *O. aestivus*. Its relative abundance probably renders *O. aestivus* susceptible to predation by many generalist predators such as *C. collaris*, which has been documented to feed on snakes (*Sonora semiannulata*; Best and Pfaffenberger 1987. Southwest. Nat. 32:415–426).

The research on *C. collaris* was partially funded by the Rob and Bessie Welder Wildlife Foundation.

SEMINATRIX PYGAEA (Black Swamp Snake). **DIET.** On 11 May 1998 we captured 29 *Seminatrix pygaea* under cover objects placed around the margins of Ellenton Bay, a 10-ha Carolina Bay on the Savannah River Site, Aiken Co., South Carolina, USA. Based on casual inspection, two females (captured between 1100 and 1200 h) appeared to contain relatively large food items, which we removed using forced regurgitation. The larger snake (451 mm SVL, 35.4 g after regurgitation) contained an undigested *Rana utricularia* (47 mm SVL, 8.0 g wet mass), a recently metamorphosed individual that had not yet completed tail resorption. The second snake (333 mm SVL, 28.7 g after regurgitation) contained a *R. utricularia* tadpole (23 mm SVL, 2.1 g wet mass; Gossner stage 37–38) and an unidentified leech.

These observations represent the first published records of *S. pygaea* preying on ranid frogs. Previous diet records include earthworms, leeches, small fishes, small frogs and tadpoles (*Acris*, *Bufo*), and salamanders (Dorcas et al. 1998. Cat. Amer. Amphib. Rept. 679.1–679.5). In the Ellenton Bay population, mosquitofish (*Gambusia affinis*) were the primary prey (82% of identified gut contents; Gibbons and Semlitsch. 1991. Guide to the Reptiles and Amphibians of the Savannah River Site. Univ. Georgia Press, Athens, Georgia. 131 pp.) prior to a drought (1985–87) that caused the extirpation of these fish (Seigel et al. 1995. Herpetologica 51:424–434). After the drought, amphibian larvae and aquatic invertebrates presumably have made up the bulk of the diet of *S. pygaea* at Ellenton Bay. Because of their size (usually <300 mm SVL), most *S. pygaea* are restricted to small prey. The two snakes reported here are near the upper end of the size range for this species (Kean and Tuberville 1995. Herpetol. Rev. 26:103), and were able to consume prey that is probably unavailable to smaller *S. pygaea*.

We thank J. Whitfield Gibbons for commenting on this note. This research was supported by Financial Assistance Award Number DE-FC09-96SR18546 from the U.S. Department of Energy to the University of Georgia Research Foundation.

THAMNOPHIS RADIX (Plains Garter Snake). **PREDATION.** There are no references specific to predation by the Virginia opossum (*Didelphis virginiana*) on live snakes. Reptiles are mentioned generically as a component of the diet of *Didelphis*, but whether they were obtained as carrion or prey was not specified (Hoffmeister 1989. Mammals of Illinois. University of Illinois Press, Urbana, Illinois. 348 pp.).

At 1445 h on 23 October 1998, I encountered a juvenile *Didelphis virginiana* in an area of open woods adjacent to a ca. 0.5-ha pond near Wheeling, Cook County, Illinois, USA. The opossum remained motionless, and upon closer approach was found to be standing over an adult female plains garter snake (*Thamnophis radix*; 51.5 cm SVL, 90 g.). The snake was immobile except for slight tail movements. Further inspection revealed a disarticulated and bleeding lower jaw and puncture wounds on the tail 3–4 cm from the anal plate.

The opossum appeared underfed and resisted minimally when captured with gloves. Its total length (snout to tip of tail) was ca. 53 cm. The *Thamnophis* was covered with damp silt, perhaps indicating recent emergence from the burrow of a crayfish (*Procambarus gracilis*) that was <1 m from the two animals. Temperatures the previous night were below 10°C, and the snake appeared sufficiently lethargic as to be unable to defend itself against attack by the opossum or to escape down the crayfish burrow. After examination, the opossum was released, and the still-living snake was retained overnight. The next morning, the snake appeared to have recovered, had re-aligned its lower jaw, and was active in the container. Bactine® was applied to the puncture wounds on the underside of the tail after the method of Martin and Hong (1991. Herpetol. Rev. 22:21). The snake was returned to the site and released.

TALLGRASS PRAIRIE SNAKE ASSEMBLAGE. FOOD HABITS. Although the natural history of most reptiles within the central Great Plains (USA) is well known (e.g., Fitch 1989. Occas. Pap. Mus. Nat. Hist. Univ. Kansas 125:1–50), few studies have been conducted on reptiles inhabiting tallgrass prairie. This lack of basic information is a major impediment to the conservation of these species (Dodd 1987. *In* Seigel et al. (eds.), Snakes: Ecology and Evolutionary Biology, pp. 478–513. Macmillan Publ. Co., New York) and the tallgrass prairie in which they exist. During a study designed to document the natural history of a tallgrass prairie rep-

tile assemblage, I was able to collect dietary information from seven snake species.

These observations were collected at the Konza Prairie Research Natural Area (3487 ha) located in Riley and Geary counties, Kansas (USA), from 1995 to 1996 (for site description see Cavitt 1998. The role of food supply and nest predation in limiting reproductive success of brown thrashers (*Toxostoma rufum*): effects of predator removal, food supplements and predation risk. Ph.D. dissertation. Kansas State Univ., Manhattan. 148 pp.). Hardware cloth drift fences connected to funnel traps were used to capture most snakes (see Cavitt, *op. cit.*, for a description of the fences and traps), although a few individuals were captured by hand. All snakes were identified, and sexed by tail shape and by probing for the presence of hemipenes. Stomach contents were examined by palpating for undigested food items. Five ungrazed sites, which had all been burned within the previous five years, were monitored for snake activity. Two of the five sites were burned by a wildfire during the study (spring 1996). A total of 550 individuals were captured, however dietary information could only be obtained from 22 individuals of seven species. Table 1 lists the food items recovered from each of the snakes captured.

Despite the fact that snake food habits are one of the most readily studied aspects of their natural history, little is known about the diet of the tallgrass prairie snake community. Invertebrates, small mammals, and bird eggs or nestlings comprised over 80% of the food items recovered; all of these are abundant within the tallgrass prairie (Kaufman et al. 1998. *In* Knapp et al. [eds.], Grassland Dynamics: Longterm Ecological Research in Tallgrass Prairies, pp. 113–139. Oxford University Press, Oxford). This supports findings from other dietary surveys suggesting food habits may be largely controlled by prey availability (e.g., Fitch 1963. Univ. Kansas Mus. Nat. Hist Misc. Publ. 15:353–468). For example, ground nesting birds are very abundant within the tallgrass prairie and bird eggs or nestlings were the only items recovered from *Pituophis catenifer* in this study. Likewise, Imler (1945. J. Wildl. Manag. 9:265–273) found that within a northern Nebraska wetland, *P. catenifer* consumed primarily waterfowl eggs. However, in the Great Basin Desert, an area with fewer ground nesting birds, *P. catenifer* rarely consumed bird eggs (Parker and Brown. 1980. Milwaukee Public Mus. Publ. Biol. Geol. 7:1–104). Although the accounts presented here are not unique for the species collected, they do provide basic information on the dietary habits of snakes inhabiting tallgrass prairie.

Many thanks to T. Miller, J. Kretzer, A. Stevens, D. Belt, M. Hill, C. Oppert, and J. Goheen for their assistance in the field. Financial support for this project was provided by an NSF Doctoral Dissertation Improvement Grant (DEB-9520335) and from the NSF Konza Prairie Long-Term Ecological Research Program (DEB-9011662).

Submitted by **JOHN F. CAVITT**, Division of Biology, Kansas State University, Manhattan, Kansas 66506, USA. Present address: Department of Zoology, Weber State University, 2505 University Circle, Ogden, Utah 84408-2505, USA; e-mail: jcavitt@weber.edu.

TABLE 1. Stomach contents of snakes captured on the Konza Prairie Reseach Natural Area. An * indicates the record was obtained from an individual captured on recently burned prairie. All other records were from snakes captured on unburned prairie.

Species	Sex	SVL (cm)	Stomach Contents

	U	25	frog (*Rana* sp.)
	U	51	*Peromyscus* sp.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins 1997. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*. Fourth Edition. SSAR Herpetol. Circ. 25:1–40; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish.* Herp. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: Joseph T. Collins (USA & Canadian records only), Kansas Biological Survey, 2041 Constant Avenue, Lawrence, Kansas 66047, USA; Jerry D. Johnson (Mexico and Central America, including the Caribbean islands), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA; Hidetoshi Ota (all Old World records), Tropical Biosphere Research Center, University of the Ryukyus, 1 Senbaru, Nishihara-cho, Okinawa 903-01, Japan; or Gustavo J. Scrocchi (South American records), Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina. Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Submissions by e-mail are encouraged where possible**. Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Marques, O. A. V., and G. Puorto. 1996. Geographic Distribution. *Chironius laevicollis*. Herpetol. Rev. 27:212.

GYMNOPHIONA

POTOMOTYPHLUS KAUPII. BRAZIL: AMAPÁ: Municipality of Macapá (00°02'N, 51°04'W), Rio Amazonas, between Fazendinha and Cascalheira. 25 May 1990. Collected by trawl net. Instituto de Pesquisas Científicas e Tecnológicas do Estado do Amapá (IEPA 030). Verified by M. Wilkinson. Previous general references to Amazon and Orinoco drainage systems of South America are in Taylor (1968, The Caecilians of the World. A Taxonomic Review. Univ. Kansas Press, Lawrence, xiv+848 pp.) and Frost (1985, Amphibian Species of the World. A Taxonomic and Geographical Reference. Allen Press, Inc., Lawrence, Kansas. vi+732 pp.). First record for the state of Amapá and for the delta of the Rio Amazonas.

Submitted by **ULISSES CARAMASCHI** and **JOSÉ P. POMBAL, JR.**, Departamento de Vertebrados, Museu Nacional/ UFRJ, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Brazil.

TYPHLONECTES COMPRESSICAUDA. BRAZIL: AMAPÁ: Região dos Lagos (01°40'N, 50°50'W). March 1984. Instituto de Pesquisas Científicas e Tecnológicas do Estado do Amapá (IEPA 027). Verified by M. Wilkinson. Previous general reference to Guyana and French Guiana to Amazon drainage of Peru and Brazil is in Frost (1985, Amphibian Species of the World. A Taxonomic and Geographical Reference. Allen Press, Inc., Lawrence, Kansas. vi+732 pp.). First record for the state of Amapá, north and outside of the Amazon drainage.

Submitted by **ULISSES CARAMASCHI** and **JOSÉ P. POMBAL, JR.**, Departamento de Vertebrados, Museu Nacional/ UFRJ, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Brazil.

CAUDATA

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: GEORGIA: Habersham Co: Nancytown Lake, 4.8 km S Mt. Airy. 26 January 1995. Carlos Camp. Georgia Museum of Natural History (GMNH 44319). Verified by M. E. McGhee. First county record (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712).

Submitted by **CARLOS CAMP**, Biology Department, Piedmont College, Demorest, Georgia 30535, USA, and **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). USA: TENNESSEE: Jackson Co: Dodson Branch, NE of Hidden Springs Nursery on Spring Creek Road at the base of Hardscrabble Falls (36°19'20"N, 85°30'42"W). 9 October 1999. Laura Leininger. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 5282 [color slide]). Two eft-stage specimens captured along the bank of Dodson Branch stream just below the falls; photographed and released. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay State Univ. Misc. Publ. 12:1–94).

Submitted by **LAURA LEININGER** and **PRIYA NANJAPPA**, Muncie Center for Medical Education, Ball State University, Muncie, Indiana 47306, USA.

ANURA

BUFO GLABERRIMUS. (Cundinamarca Toad). PERU: DEPARTAMENTO UCAYALI: Provincia de Atalaya: ca. 22 km E Bolognesi (10°06'S, 73°49'W, 230 m elev.). 11 June 1998. Edgar Lehr. Natur-Museum und Forschungs-Institut Senckenberg (SMF 80009). Verified by Javier Icochea. First state record (Rodríguez et al. 1993, Publ. Mus. Hist. Nat. UNMSM [A] 45:1–22).

Submitted by **EDGAR LEHR** and **GUNTHER KÖHLER**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a. M., Germany, (e-mail [EL]: elehr@sng.uni-frankfurt.de).

ELACHISTOCLEIS OVALIS. VENEZUELA: ZULIA: Río Escalante, Hacienda Santa Rosa, 70 m elev. 20 December 1986. A. Díaz and P. Durant. Colección de Vertebrados, Facultad de Ciencias Universidad de los Andes, Mérida (CVULA 4873). Verified by Andrés Orellana. *Elachistocleis ovalis* has been known in Venezuela from three bioregions (Barrio 1998, Acta Biol. Venezuela 18[2]:1–93) as follows: "región Llanera" (the Great plains), "región Guayanesa" (savanna in Guianan shield), and "región Orocostense" (the Coastal Range), the latter a characteristic savanna batrachological element rising up to 1000 m elevation in some places of Andean and coastal piedmonts. The "Hoya de Maracaibo" region (Barrio, *op. cit.*) is isolated by two high chains of the Andean range, the Cordillera de Mérida in the southeast, and the Sierra de Perijá in the west. This is the first documented voucher and the only microhylid record for this region in Venezuela.

Submitted by **CÉSAR LUIS BARRIO**, Fundación Andígena, Apartado Postal 210, 5101-A Mérida, Venezuela (e-mail: cesarlba@yahoo.com), and **PEDRO DURANT**, Grupo de Ecología Animal, Departamento de Biología, Facultad de Ciencias, Universidad de los Andes, Mérida, Venezuela.

GASTROPHRYNE OLIVACEA. (Great Plains Narrowmouth Toad). USA: NEW MEXICO: Union Co: Kiowa National Grasslands just W USFS Unit 49, 36°33'09.5"N, 103°07'38.6"W. 6 August 1999. Emily C. Moriarty, Suzanne L. Collins, and Joseph T. Collins. KU 288999. Verified by John E. Simmons. Single adult male calling from ephmeral pool. Third known New Mexico locality and the first record for the northern half of the state (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **EMILY C. MORIARTY**, Department of Biology, Saint Mary's College, Notre Dame, Indiana 46556, USA, and **SUZANNE L. COLLINS**, The Center for North American Amphibians and Reptiles, 1502 Medinah Circle, Lawrence, Kansas 66047, USA, and **JOSEPH T. COLLINS**, Kansas Biological Survey, 2045 Constant Avenue, Lawrence, Kansas 66047, USA.

HYLA PUNCTATA (Rana Punteada, Polkadot Treefrog): VENEZUELA: ESTADO BARINAS: Barinitas, 600 m. 16 June 1990. A. J. Cardoso and J. Péfaur. Colección de Vertebrados, Facultad de Ciencias Universidad de los Andes, Mérida (CVULA 5280). Reserva de Fauna, Sabanas de Anaro. 28 October 1994. R. Rivero. Museo de la Estación Biológica Rancho Grande, MARNR, Maracay (EBRG 2850, 2856). Both verified by Andrés Orellana. ESTADO BOLIVAR: Reserva Forestal Imataca, 40 km ENE Tumeremo. 11 September 1990. A. Mijares and J. Ochoa. EBRG 267. Verified by Oswaldo Fuentes. First state records for Barinas. Species was previously known from three localities in Venezuela, two from the delta of the state of Amacuro (Orinoco delta) and another from the state of Bolivar (Hoogmoed 1979, Zool. Verh. 172:1–46; Barrio 1998, Acta Biol. Venezuela 18[2]:1–93). These records corroborate presence of species in lowlands, up to 600 m in Venezuela, including the Llanos and the foothills of the Andes, some 1000 km W of the former referred localities. To date, the species is known in four bioregions (sensu Barrio, *op. cit.*), the Andean, Delta, Llanos and Guayanan.

Submitted by **CÉSAR LUIS BARRIO**, Fundación Andígena, Apartado Postal 210, 5101-A, Mérida, Venezuela (e-mail: cesarlba@yahoo.com), **RAMÓN RIVERO**, Museo de la Estación Biológica Rancho Grande, MARNR, Maracay, Venezuela, and **ROGER MANRIQUE**, Fundación Andígena, Apartado Postal 210, 5101-A, Mérida, Venezuela.

LEPTODACTYLUS FLAVOPICTUS. BRAZIL: SANTA CATARINA: Guaramirim Municipality, Atlantic Rain Forest, 26°27'S, 49°00'W. 24 July 1999. Germano Woehl Jr. KU Color Slide 11726. Verified by José Peres Pombal, Jr. First record for the state and Atlantic forests of southern Brazil.

Submitted by **GERMANO WOEHL, JR**. and **ELZA N. WOEHL**, Santuario Ra-bugio, Estrada Rio da Prata, 89290-000 Guaramirim, Santa Catarina, Brazil (e-mail: germano@ieav.cta.br).

PSEUDACRIS CLARKII (Spotted Chorus Frog). USA: ILLINOIS: McLean Co: Moraine View State Park, 0.25 km NW of Dawson Lake along a creek (NW 1/4, SW 1/4, Sec. 26, T23N, R4E). 6 April 1999. H. M. Burdett. Illinois Natural History Survey (INHS 15044). Verified by L. E. Brown. First record of *P. clarkii* in Illinois; closest locality is Montgomery County, Kansas, ca. 700 km to the southwest (Collins 1993, Amphibians and Reptiles in Kansas. Third ed. Univ. Press of Kansas, Lawrence. xx + 397 pp.). A single adult male (26 mm SVL) was collected. It was probably introduced as a tadpole along with fish during stocking the previous year. There was no evidence of a breeding population in the spring and summer of 1999.

Submitted by **DONALD B. SHEPARD** and **HERBERT M. BURDETT**, Department of Biological Sciences, Illinois State University, Normal, Illinois 61790-4120, USA.

PSEUDACRIS CRUCIFER. (Spring Peeper). USA: KANSAS: Miami Co: SW 1/4 SW 1/4 Sec. 26, T17S, R25E. 14 April 1999. Keith Coleman. KU 288855–856; NW 1/4 Nw 1/4 Sec. 34, T17S, R25E. 14 April 1999. Keith Coleman. KU 288857. All verified by Joseph T. Collins. Single adult males taken as vouchers from choruses. Discovery of these populations corroborates a 71-year-old record (UMMZ 72390) from Pigeon Lake in the same county on 6 April 1929.

Submitted by **KEITH COLEMAN**, 2429 Ousdahl Road, Lawrence, Kansas 66046-4052, USA.

RANA GRYLIO (Pig Frog). PUERTO RICO: TOA BAJA: SABANA SECA: wetland area known as Ciénaga de San Pedro, 2.9 km on Rt. 867 within the North Tract sector of the U.S. Naval Security Group Activity (18°27'04"N, 66°12'42"W). 12 November 1998. Neftalí Rios-López. Verified by Julian C. Lee. Museu de Biología, Universidad de Puerto Rico-Recinto de Río Piedras. (UPRRP 5752, 5754). First record for Puerto Rico and the southeasternmost record for the species. A female (111.7 mm SVL) and a juvenile (68.6 mm SVL) were collected at 2200 h from a flooded channel, which runs parallel to a side road within the North Track area. Calling males were heard in March, August, and September 1995, and in October and November 1998. Females, subadults, and juveniles were observed while submerged (partially or up to the head) in open waters surrounded by vegetation. However, calling males were heard from within large clumps of *Typha dominguensis* and these animals were not seen openly exposed

while calling. The calling behavior might explain why the species was not previously reported and probably calling individuals were confused with birds calling within vegetation clumps throughout the area. *Rana grylio* is present also in the Tortugero Lagoon Reserve and associated nearby wetlands (Manati/Vega Baja, Tierras Nuevas Saliente, Rt. 686, 18°28'00"N, 66°27'48"W). A subadult (102.7 mm SVL, UPRRP 5761) and a juvenile (40.4 mm SVL, UPRRP 5762) were collected by Carlos Toledo and NRL (17 August 1999) at the edges of a small pool surrounded by *T. dominguensis*. Finally, the species was also found all along the Caño Tiburones (water channel which cuts through an associated wetland area) at the northwesternmost part of its geographic distribution within Puerto Rico (Arecibo, Factor, Rt. 682, 18°27'47"N, 66°38'21"W). A juvenile (53.6 mm SVL, UPRRP 5763) was collected (NRL) from within the channel on which males were heard calling in the water.

These data indicate that *R. grylio* is well established in northern Puerto Rico and it is reproductively active during most of the year. This frog ranges from southeastern South Carolina to southeastern Texas, and has been also introduced on Andros and New Providence islands in the Bahamas (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Sumitted by **NEFTALÍ RIOS-LÓPEZ** and **RAFAEL L. JOGLAR**, Universidad de Puerto Rico, Recinto de Río Piedras, Departamento de Biología, Apartado 23360, San Juan, Puerto Rico 00931-3360.

RANA SYLVATICA (Wood Frog). USA: TENNESSEE: Jackson Co: Dodson Branch, NE of Hidden Springs Nursery on Spring Creek Rd. near Dodson Branch (36°19'20"N, 85°30'42"W). 9 October 1999. Priya Nanjappa. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 5283 [color slide]). Adult captured in leaf litter of a mixed forest near Dodson Branch; photographed and released. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay State Univ. Misc. Publ. 12:1–94).

Submitted by **PRIYA NANJAPPA** and **LAURA LEININGER**, Muncie Center for Medical Education, Ball State University, Muncie, Indiana 47306, USA.

SCINAX RUBRA. PUERTO RICO: TOA BAJA: SABANA SECA: wetland area known as Ciénaga de San Pedro, 2.9 km on Rt. 867 within the North Tract sector of the U.S. Naval Security Group Activity (18°27'30"N, 66°12'30"W). 12 November 1998. Neftalí Rios-López. Verified by Rafael L. Joglar. Museu de Biología, Univerisdad de Puerto Rico-Recinto de Río Piedras (UPRRP 5753, 5755–58). New record for the northcentral part of Puerto Rico. Five calling males (SVL 28.86 ± 1.19 mm, min. 27.4 mm, max. 30.4 mm) were collected at 2030 h from a flooded area two to three meters above sea level along both sides of a local road within the North Track area. Species is abundant within the more than 16 km^2 this wetland covers. These data suggest that the population is established and reproductively active throughout the year. The new geographic area reported herein is the northwesternmost record for the species. A previous report on its geographical range within Puerto Rico included the Bayamón-Carolina area (Rivero 1998, Los Anfibios y Reptiles de Puerto Rico/ The Amphibians and Reptiles of Puerto Rico. Segunda Ed. Editorial Universitaria U. P. R., San Juan. 510 pp.).

Sumitted by **NEFTALÍ RIOS-LÓPEZ**, Universidad de Puerto Rico, Recinto de Río Piedras, Departamento de Biología, Apartado 23360, San Juan, Puerto Rico 00931-3360.

TESTUDINES

APALONE SPINIFERA SPINIFERA (Eastern Spiny Softshell). USA: KENTUCKY: Campbell Co: Alexandria, jct. California Crossroads and Wesley-Chapel Roads, in 12-mile Creek, a second order stream; others seen in area (38°53'20"N, 84°18'35"W). 8 June 1998. C. Lorentz. AMEIVA EDRACANTHA (Bocourt's Ameiva). PERU: ANCASH: PROVINCIA HUARMEY: Huamba Alta (09°57'S, 77°51'W, 710 m elev.). 9 February 1997. Edgar Lehr. Natur-Museum und Forschungs-Institut Senckenberg (SMF 80011); Janca (09°46'S, 77°57'W, 870 m elev.). 16 March 1997. Edgar Lehr. SMF 80013; Huarmey (10°04'S, 78°10'W, 20 m elev.). 17 May 1998. Edgar Lehr. SMF 80014. PROVINCIA BOLOGNESI: Cajacay (10°10'S, 77°27'W, 2335 m elev.). 30 March 1997. Edgar Lehr. Museo de Historia Natural de San Marcos (MHNSM 20039). All verified by Gunther Köhler. First state record, and southernmost record for Peru (Carrillo de Espinoza and Icochea 1995, Publ. Mus. Hist. Nat. UNMSM [A] 49:1–27).

Submitted by **EDGAR LEHR**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a. M., Germany (e-mail: elehr@sng.uni-frankfurt.de) and **CESAR AGUILAR**, Museo de Historia Natural, Departamento de Herpetologia, Universidad Nacional Mayor de San Marcos, Avenida Arenales 1256, Jesus Maria, Apartado 14-0434, Lima, Peru.

CNEMIDOPHORUS LACERTOIDES. ARGENTINA: ENTRE RIOS: Departamento Diamante: Diamante (32°04'S, 60°39'W). S. L. De Frers. 29 December 1924. Herpetological collection Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Buenos Aires, Argentina (MACN 4511). Verified by G. Carrizo. First provincial record; extends known range 400 km NW of previous records (Cei and Martori 1991, Boll. Mus. reg. Sci. nat. Torino. 9[1]:33–38; Aún and Martori 1996, Cuad. Herpetol. 9[2]:95–99; Cei 1993, Boll. Mus. reg. Sci. nat. Torino. Monograf. XIV:362–385; Gallardo, Miranda and Tio Vallejo 1987, Revta. Mus. arg. Cs. nats. Bermardino Rivadavia Cienc. Zool. 14[5]:88–94).

Submitted by **LUCIA FEDERICO**, Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Angel Gallardo 490, Buenos Aires, Argentina (e-mail: luciafed@hotmail.com or amf@fibertel.com.ar).

COSYMBOTUS PLATYURUS (Asian House Gecko). USA: FLORIDA: ALACHUA CO: 1800 block of NE 23rd Avenue, Gainesville. No date given. J. Brian Hauge and Brian P. Butterfield. Auburn University Museum (AUM 35156–57). Verified by R. D. Bartlett. Several individuals observed, two adults collected from warehouses near former location of Hogtown Herpetological Supply. As the herpetological supply business here closed several years ago, and specimens of various sizes were observed, we suspect that a reproductively active colony occurs at this site. New county record.

Submitted by **J. BRIAN HAUGE**, Department of Biology, Penn State University at Hazleton, Hazleton, Pennsylvania 19201-1291, USA, and **BRIAN P. BUTTERFIELD**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

EUMECES LATICEPS (Broadhead Skink). USA: KANSAS: NEOSHO CO: Sec. 22, T30S, R20E. 28 April 1978. N. J. Hilscher. Sternberg Museum of Natural History (MHP 5757). Verified by Kelly J. Irwin. New county record for this Kansas threatened species (Collins 1993, Amphibians and Reptiles in Kansas. Third Edition. Univ. Press Kansas, Lawrence. xx + 397 pp.).

Submitted by **TRAVIS W. TAGGART**, Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas 67601, USA, and **JOSEPH T. COLLINS**, Kansas Biological Survey, 2041 Constant Avenue, Lawrence, Kansas 66047, USA.

GEKKO GECKO (Tokay Gecko). USA: FLORIDA: ALACHUA CO: 1800 block of NE 23rd Avenue, Gainesville. 14 May 1999. Brian P. Butterfield and J. Brian Hauge. Auburn University Museum (AUM 35155). Verified by R. D. Bartlett. Juvenile collected from warehouses near former location of Hogtown Herpetological Supply. As the herpetological supply business here closed several years ago, and the specimen collected was a juvenile, we suspect that a small breeding colony occurs here. New county record (Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89).

Submitted by **BRIAN P. BUTTERFIELD**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA, and **J. BRIAN HAUGE**, Department of Biology, Penn State University at Hazleton, Hazleton, Pennsylvania 19201-1291, USA.

HEMIDACTYLUS FRENATUS. HONDURAS: ATLANTIDA: La Ceiba, found at night on the wall of the Hotel Partenon. 5 June 1997. C. J. Franklin. University of Texas at Arlington (UTA R-42657). First record for department; CORTES: Oropendoles, ca. 650 m elev. 18 December 1996. E. N. Smith. UTA R-41280. Both verified by J. A. Campbell. First record for county.

Submitted by **CARL J. FRANKLIN**, Department of Herpetology, Dallas Zoo, 650 South R. L. Thornton Freeway, Dallas, Texas 75203, USA (e-mail: herpking@ix.netcom.com).

HEMIDACTYLUS MABOUIA (Tropical Gecko). ARGENTINA: CHACO: Departamento San Fernando: Resistencia (29°27'S, 58°59'W). P. M. Cacivio. 22 March 1999. Herpetological collection Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Buenos Aires, Argentina (MACN 37129). Verified by G. Carrizo. First provincial record; extends known range 500 km SW from the previous known records (Genise and Montanelli 1991, Bol. A. H. A 7[1]:23; Cei 1993, Boll. Mus. reg. Sci. nat. Torino. Monograf. XIV:329–336; De Avila Pires 1995, Amazonia. Zool. Verh. Leiden 299:228–238).

Submitted by **LUCIA FEDERICO**, Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Angel Gallardo 490, Buenos Aires, Argentina (e-mail: luciafed@hotmail.com or amf@fibertel.com.ar) and **PEDRO. M. CACIVIO**, Centro Productor de Suero Antiofidico (CE.P.S.AN), Costanera 99, Corrientes, Argentina (e-mail: cacivio@hotmail.com or cacivio@arnet.com.ar).

HEMIDACTYLUS MABOUIA (Tropical Gecko). USA: FLORIDA: ORANGE CO: Wekiwa Springs State Park. 12–13 May 1999. Brian P. Butterfield and J. Brian Hauge. No date given. Auburn University Museum AUM 35151–54. Verified by R. D. Bartlett. Several individuals observed on campground bathhouses at night. Specimens collected were two adult males, one gravid female, and one juvenile. Specimens of *H. garnotii* were also observed. New county record.

Submitted by **BRIAN P. BUTTERFIELD**, **ISRAEL FOX**, **JONATHAN GARNER**, and **KYLE CARTER**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA, and **J. BRIAN HAUGE**, Department of Biology, Penn State University at Hazleton, Hazleton, Pennsylvania 19201-1291, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). SOUTH CAROLINA: CHARLESTON CO: West Ashley residential community, Village Road (32°48.300'N, 80°00.434'W). Captured and photographed 12 July 1998. George W. Eason, Jr.; West Ashley residential community, Treescape Drive (32°50.665'N, 80°03.157'W). 18 December 1998. Dorian R. McMillan. ChM CR 2643; West Ashley residential community, Village Road (32°48.300'N, 80°00.434'W). 14 June 1999. Dorian R. McMillan and George W. Eason, Jr. ChM CR 2644. Confirms first capture (12 July 1998) which lacks a specimen voucher. Many individuals of different size classes have been observed at these sites. Both specimens verified by Albert Sanders. First records for the state (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin, Boston, Massachusetts. 616 pp.). These records represent the northernmost distribution of the species for the southeastern U. S., ca. 130 km (airline) northeast of the previous record in Chatham County, Georgia. (Frick 1997, Herpetol. Rev. 28:50).

Submitted by **GEORGE W. EASON, JR.**, South Carolina Department of Natural Resources, Land, Water and Conservation Division, 1201 Main Street, Columbia, South Carolina 29201, USA, and **DORIAN R. McMILLAN**, College of Charleston, Department of Biology, 66 George Street, Charleston, South Carolina 29424, USA.

LEIOCEPHALUS CARINATUS ARMOURI (Northern Curlytail Lizard). USA: FLORIDA: MARTIN CO: on grounds of Sea Treasures tourist shop, 18955 US Rt. 1. 16 May 1999. J. Brian Hauge and Brian P. Butterfield. Auburn University Museum (AUM 35158). Verified by Craig Guyer. Several individuals observed; one adult male collected. New county record (Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89).

Submitted by **J. BRIAN HAUGE**, Department of Biology, Penn State University at Hazleton, Hazleton, Pennsylvania 19201-1291, USA, and **BRIAN P. BUTTERFIELD**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

LIOLAEMUS RIOJANUS. ARGENTINA: SAN JUAN: Ullum Department: 34 km from San Juan City on Bolson de Matagusanos (31°19'S, 68°41'W). March 1998. J. C. Acosta. Herpetological Collection, Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Argentina (IMCN-UNSJ 384, male). Verified by Ricardo Martori. Extends the known range (Cei 1993, Mon. XIV Mus. Reg. Sci. Nat. Torino, 949 pp.) ca. 60 km northwest of Caucete.

Submitted by **JUAN CARLOS ACOSTA** and **FERNANDO MURÚA,** Departamento de Geofísica y Astronomía e Instituto y Museo de Ciencias Naturales, F.C.E.F. y N, Universidad Nacional de San Juan, Avenida España 400 (N). Caixa Postal 5400, San Juan, Argentina.

MABUYA FRENATA. BRAZIL: TOCANTINS: Parque Estadual do Cantão, along the Araguaia river (9°27'S, 49°50'W). 21 September 1999. Maria Goretti M. Pinto. Herpetological Collection, University of Brasília, Distrito Federal, Brazil (CHUNB 12401). Verified by Guarino R. Colli. Species has been recorded from widespread localities in South America, but this is the northernmost record, at a locality the border between Cerrado and Amazonia habitat. Two individuals, possibly fighting or trying to copulate, were seen in the morning, on the leaf litter along a trail of an open forest, but just one (male) was captured.

Submitted by **MARIA GORETTI M. PINTO** and **ALEXANDRE B. ARAUJO**, Departamento de Zoologia, Universidade de Brasília, 70910-900, Brasília, Distrito Federal, Brazil.

OPHIODES VERTEBRALIS. ARGENTINA: SANTIAGO DEL ESTERO: Departamento Figueroa: Caspi Corral (27°37'S, 63°31'W). 21 December 1987. J. Soroka. Herpetological collection of Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Buenos Aires, Argentina (MACN 34249). Verified by G. Carrizo. Departamento Belgrano: Malbran (29° 21'S, 62° 27'W).

December 1978, J. Soroka (MACN 34576). First province records, extend known range 400 Km N from previous records (Cei 1993, Boll. Mus. reg. Sci. nat. Torino, Monograf. XIV:418–421; Gallardo 1966, Mus. arg. Cs. nats. Bermardino Rivadavia [Cienc. Zool.] 9[6]:124–146; Gallardo et al., 1985, Hist. Nat. Corrientes Argentina 5[13]:97–103).

Submitted by **LUCIA FEDERICO**, Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Angel Gallardo 490, Buenos Aires, Argentina (e-mail: luciafed@hotmail.com or amf@fibertel.com.ar).

PHRYNOSOMA ORBICULARE (Mountain Horned Lizard). MÉXICO: GUERRERO: San Juan de las Joyas, Municipio de Ahuacuotzingo, (17°50'N, 99°04'W), 1200 m elev. 24 May 1998. Elizabeth Beltrán Sánchez. Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México, IBH 12451, 12452 (SVL 86 and 68 mm, TL 37 and 41 mm, respectively), adults, female, and male found in a disturbed oak forest. Both specimens verified by Víctor Hugo Reynoso Rosales. First record for state and not previously reported in the checklist by Saldaña de la Riva and Pérez-Ramos (1987, Herpetofauna del Estado de Guerrero, México. México, UNAM Tésis Prof. 389 pp.); extends range ca. 190 km SW and 155 km S from the closest known localities in San Diego Chalma, SE of Tehuacán, Puebla, and near Tres Marías (Km 57), Morelos, respectively (Smith and Taylor 1950, U.S. Natl. Mus. Bull. 199:1–253; Reeve 1952, Univ. Kansas Sci. Bull. 34[14]:817–960; Horowitz 1955, American Midl. Nat. 54:204–218; Baur and Montanucci 1998, Herpeton. Verlag Elke Köhler. Offenbach). This Guerrero population may be a relic of a formerly wider range for this lizard that linked the populations of Morelos and Puebla, which are currently recognized as two subspecies (*P. o. orbiculare* in Morelos and *P. o. cortezi* in Puebla), and may have significance in resolving the status of the subspecific taxa.

Submitted by **ELIZABETH BELTRÁN SÁNCHEZ**, Instituto de Investigaciones Científicas Area de Ciencias Naturales, Universidad Autónoma de Guerrero, Avenida Lazaro Cardenas S/N, Ciudad Universitaria, Interior del Jardín Botánico, Caixa Postal 39000, Chilpancingo, Guererro, México (e-mail: ebeltran@galeana.uagfm.mx), **FERNANDO MENDOZA QUIJANO**, Instituto Tecnológia Agropecuario No. 6, Km 5.5 Carr. Huejutla-Chalahuiyapa, Apartado Postal 94, Caixa Postal 43000, Huejutla de Reyes, Hidalgo, México (e-mail: mendozaq@mail.ibiología.unam.mx), and **WADE C. SHERBROOKE**, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA (e-mail: wcs@amnh.org).

PHYLLOPEZUS PERIOSUS. BRAZIL: PERNAMBUCO: Municipality of Ibimirim (08°30'23"S, 37°42'46"W). October 1998. J. P. Pombal, Jr., O. C. Oliveira, and R. N. Feio. Museu Nacional-Rio de Janeiro (MNRJ 7381–85). PARAIBA: Municipality of Congo (07°48'01"S, 36°40'46"W). October 1998. J. P. Pombal, Jr., O. C. Oliveira, and R. N. Feio. MNRJ 7386–89. RIO GRANDE DO NORTE: Municipality of Serra Negra do Norte (06°33'–06°37'S, 37°14'–37°16'W). May 1999. A. A. Varela-Freire and B. Maggi. Coleção Taxonômica Interiorana da Estação Ecológica de Seridó (CTI-EES 3117–18). ALAGOAS: Municipality of Piranhas (09°28'–09°36'S, 37°47'–38°03'W). June 1994. Equipe Resgate de Fauna UHE Xingó. Museu de História Natural da Universidade Federal de Alagoas (MUFAL 1305, 1307–09). All verified by U. Caramaschi and R. Fernandes. Previously published distribution of the species was restricted to Cabaceiras (state of Paraíba) and Sítio dos Nunes (state of Pernambuco), suggesting a relictual distribution (Rodrigues 1986, Pap. Avuls. Zool. 36[20]:237–250). These new records expand significantly the known distribution and represent the first records for the states of Alagoas and Rio Grande do Norte.

Submitted by **ELIZA MARIA XAVIER FREIRE**, Departamento de Zoologia e Museu de História Natural, Universidade Federal de Alagoas, Rua Aristeu de Andrade, 452, 57021-090 Maceió, Alagoas, Brazil, **RENATO NEVES FEIO**, Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, 36571.000 Viçosa, Minas Gerais, Brazil, and **JOSÉ P. POMBAL, JR.**, Museu Nacional/UFRJ, Quinta da Boa Vista, 20.940-040 Rio de Janeiro, Brazil.

SERPENTES

COLUBER CONSTRICTOR LATRUNCULUS (Blackmask Racer). USA: TENNESSEE: Shelby Co: T. O. Fuller State Park (35°04'04"N, 90°07'27"W), grassy bank at the terminus of Mitchell Road, 8 m down slope from W shoulder of road: One predated specimen (APSU 5292). 18 April 1998. Donald L. Thomas; Second individual (APSU color slide 5290) collected same location. 10 June 1999. James T. Eubanks, Keith W. Pecor, and Donald L. Thomas; Edward J. Meeman Biological Station (35°21'05"N, 90°01'32"W), brush piles 40 m from W side of station: Three specimens (APSU color slides 5291a–c) collected from under woody debris. 18 May 1999. James T. Eubanks; Loosahatchie Biological Station (35°15'34"N, 89°48'32"W), woody debris in an open field 55 m N of Old Brownsville Road: Five individuals (APSU color slide 5293) including two gravid females. 20 May 1999. James T. Eubanks. All snakes listed above were considered adults (snout-vent length >90 cm). All specimens were verified by William H. N. Gutzke. New state record; northern range limit for this subspecies is reported as northern Mississippi (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd Ed. expanded. Houghton Mifflin Co, Boston, Massachusetts. 616 pp.).

Submitted by **DONALD L. THOMAS**, **JAMES T. EUBANKS**, and **KEITH W. PECOR**, Department of Biology, University of Memphis, Memphis, Tennessee 38152, USA.

CROTALUS ATROX (Western Diamondback Rattlesnake). USA: ARIZONA: Mohave Co: Grand Canyon, confluence of Diamond Creek and Colorado River: river mile (RM) 225.7: 35°46'N, 113°22'W. Summer 1997. William Walls. KU Color Slide 11725. Verified by Bruce Gomes. First verified record in the Grand Canyon. Miller et. al. (1982, Amphibians and Reptiles of the Grand Canyon. Publ. Grand Canyon Natural History Association. 114 pp.) make no reference to *C. atrox* inhabiting the Grand Canyon (Lee's Ferry to Lake Mead). Grater (1981. Snakes, Lizards, and Turtles of the Lake Mead Region. Publ. Southwest Parks and Monuments Association. 47 pp.) suggests that *C. atrox* is uncommon and has been found only in the southern part of the Lake

Mead-Lake Mojave Region. Lowe et. al. (1986, The Venomous Reptiles of Arizona. Publ. Arizona Game and Fish Department, Phoenix. 115 pp.) show the northern distribution of *C. atrox* as extending north of Peach Springs towards the Colorado River, but not to the river itself.

Submitted by **NIKOLLE L. BROWN**, 7779 North Leonard, Clovis, California 93611, USA.

CROTALUS MOLOSSUS (Blacktail Rattlesnake). USA: ARIZONA: Coconino Co: Colorado River, Lower Lava rapids, river mile (RM) 179.8, south rim: 36°11'N, 113°07'W. Summer 1991. John Running. KU Color Slide 11722. Verified by Cecil Schwalbe. Only one other specimen (SDSNH Z06066) referenced in the literature documents the occurence of *C. molossus* within the Grand Canyon (McKee and Bogert 1934, Copeia 1934:178–180.). However, Lowe et al. (1986, The Venomous Reptiles of Arizona. Arizona Game and Fish Department, Phoenix. 115 pp.) illustrate a range which includes the Grand Canyon region (north and south side of the river) from Pierce Ferry (RM 280) east to Havasu Canyon (RM 156.8), although these authors do not cite voucher specimens. This voucher slide provides the first evidence that *C. molossus* occurs down to river level in the Canyon. Two additional recent photographic vouchers of *C. molossus* from the Peach Springs road (KU Color Slides 11723–724) suggest this species may be more common above the river in the western Grand Canyon than indicated by the previous dearth of voucher specimens.

Submitted by **NIKOLLE L. BROWN**, 7779 North Leonard, Clovis, California 93611, USA.

DIADOPHIS PUNCTATUS REGALIS (Regal Ringneck Snake). USA: ARIZONA: Mohave Co: Grand Canyon: Fall Canyon: ca 0.25 mi. from Colorado River, river mile (RM) 211.5: 35°56'N, 113°20'W. August 1999. Daniel Hall. KU Color Slide 11728. Verified by Cecil Schwalbe. First verified record from the Grand Canyon. There are no references to *Diadophis punctatus* inhabiting the Grand Canyon (Lee's Ferry to Lake Mead; Miller et. al. 1982. Amphibians and Reptiles of the Grand Canyon. Grand Canyon Nat. Hist. Assoc. 114 pp.) or the Lake Mead-Lake Mojave Region (Grater 1981. Snakes, Lizards, and Turtles of the Lake Mead Region. Southwest Parks and Monuments Assoc. 47 pp.). Both Stebbins (1985, Peterson Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.) and Lowe et al. (1986, The Venomous Reptiles of Arizona. Arizona Game and Fish Department, Phoenix. 115 pp.) suggest there are only local populations of this species in northwestern Arizona.

Submitted by **NIKOLLE L. BROWN**, 7779 North Leonard, Clovis, California 93611, USA.

DRYMOLUBER DICHROUS. BRAZIL: ALAGOAS: Maceió (9°40'S, 35°43'W). 25 April 1996. Museu de História Natural, Universidade Federal de Alagoas (MUFAL 1460); Rio Largo (9°30'S, 35°50'W). 23 February 1994. MUFAL 462. 1 October 1994. MUFAL 1420. Eliza M. X. Freire, Selma T. Silva, and Edelmo M. Gonçalves. Both found in small patches of Atlantic Forest. All verified by Ronaldo Fernandes. First record for the northeastern Brazil; extends the range of the species ca. 1500 km SE Belém, Pará, Brazil (Cunha and Nascimento 1978, Publ. Avuls. Mus. Par. Emílio Goeldi 31:79–80).

Submitted by **ELIZA MARIA XAVIER FREIRE**, Departamento de Zoologia e Museu de História Natural, Universidade Federal de Alagoas, Rua Aristeu de Andrade, 452, Maceió, Alagoas, 57021-090, Brazil, and Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil.

GASTROPYXIS SMARAGDINA (Emerald Snake). TANZANIA: Arusha Region: Minziro Forest Reserve, 1°05'S, 31°30'E. October 1998. A. Berggreen, M. Andersen, and P. Gravlund. ZMUC R602527. Verified by Jens Bødtker Rasmussen (following Pittman 1974). First record from Tanzania. Known from Uganda, Eastern Zaire, and West Africa (Pittman 1974, Guide to the Snakes of Uganda. Codicote, Wheldon & Wesley, Ltd.). The new record is situated ca. 180 km to the SW of the closest known locality in Uganda (Bunjako Island, Pittman 1974, *op. cit.*).

Submitted by **PETER GRAVLUND**, The Zoological Museum, Vertebrate Department, Herpetological Section, University of Copenhagen, Universitetsparken 15, DK-2100, Copenhagen, Denmark.

HYPSIGLENA TORQUATA (Night Snake). MEXICO: BAJA CALIFORNIA NORTE: Isla Salsipuedes, Gulf of California, SW portion of island (28°44'N, 112°59'W). 31 March 1999. Allen McAfee and Jim Gilardi. Verified by Clark R. Mahrdt. LACM-PC 1332. Specimen was found under a rock next to a freshly killed *Uta stansburiana*. Species has also been reported from the nearby islands of San Esteban and San Lorenzo Sur in the Midriff Archipelago in addition to several islands throughout the Gulf of California (Grismer 1999, Bull. So. California Acad. Sci. 98: 45–56); represents the first record for Isla Salsipuedes.

Submitted by **ALLEN McAFEE**, 2144 Bancroft Street, San Diego, California 92104-5606, USA, and **JIM GILARDI**, Life Sciences Department, Palomar College, 1140 West Mission Road, San Marcos, California 92069, USA (e-mail: jgilardi@palomar.edu).

IMANTODES CENCHOA (Blunthead Tree Snake). BRAZIL: SANTA CATARINA: Municipality of Blumenau (26°56'S; 49°03'W, 20 m elev.). Two specimens: March 1986. M. A. Baptista, Herpetological Collection Museu de História Natural Capão da Imbuia, Curitiba (MHNCI 1961); 1996. H. Berckenbrock (MHNCI 7663). Municipality of Ibirama: (27°04'S; 49°31'W, 150 m elev.) 24 July 1990. D. Polini (MHNCI 8322). Municipality of Corupá: "Humboldt" (= Municipality of Corupá, 26°26'S; 49°14'W, 60 m elev.) 25 January 1916. W. Ehrhardt. Museu Nacional do Rio de Janeiro (MNRJ.448). All verified by Ronaldo Fernandes. All records are in the Atlantic Forest Domain. Species was recently recorded from southeastern and southern Brazil, from the states of São Paulo and Paraná (Marques 1996, Herpetol. Rev. 27:34; Moura-Leite et al. 1996, Herpetol. Rev. 27:216). First state records; extend range ca 180 km S nearest known locality in the state of Paraná (Piraquara Municipality, Volta Grande; Moura-Leite et al., *op. cit.*).

Submitted by **RENATO SILVEIRA BÉRNILS**, Sociedade Fritz Müller de Ciências Naturais, Caixa Postal 1644-80001-970, Curitiba, Paraná, Brazil (e-mail: bernils@ xmail.com.br), **SÉRGIO**

AUGUSTO ABRAHÃO MORATO, Companhia Paranaense de Energia (COPEL), Superintendência de Engenharia-Meio Ambiente, Rua Voluntários da Pátria, 233, 7º Andar-80020-942, Curitiba, Paraná, Brazil, and Museu de História Natural Capão da Imbuia (e-mail: samorato@mail.copel.br), and **JULIO CESAR DE MOURA-LEITE**, Laboratório de Herpetologia, Museu de História Natural Capão da Imbuia, Departamento de Zoológico (SMMA/PMC), Rua Prof. Benedito Conceição, 407-82810-080 Curitiba, Paraná, Brazil, and Curso de Pós-Graduação em Zoologia, Universidade Federal do Paraná, Curitiba, Paraná, Brazil (e-mail: mleit@uol.com.br).

LAMPROPELTIS GETULA (Common Kingsnake, Culebra Real Común). MÉXICO: BAJA CALIFORNIA SUR: Isla Santa Cruz, 25°15'40.7"N, 110°43'39.9"W. 5 September 1999. L. Lee Grismer. Verified by Francisco Reynoso. LSUHC-PC S2349. A carcass of one individual was found at 0630 h on the SW side of the island in a narrow, rocky arroyo. The most recent checklist of amphibians and reptiles from the Gulf of California does not include this species from Isla Santa Cruz (Grismer 1999, Bull. South. California Acad. Sci. 98:45–56).

Submitted by **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515, USA, and **BRADFORD D. HOLLINGSWORTH**, P.O. Box 121390, Department of Heretology, San Diego Natural History Museum, San Diego, California 92119-1390, USA.

LEPTOTYPHLOPS DULCIS (Texas Blind Snake). USA: KANSAS: KIOWA CO: NW1/4 Sec. 8, T30S, R16W. 25 June 1999. Derek Moeller, Allie Kossoy, and Whitney Hamilton. (KU 289043). Verified by Joseph T. Collins. A juvenile found under a rock on S facing hillside ca. 1 mi NW Belvidere at 1200 h on 25 June 1999. Soil beneath rock was soft, sandy, and moist. An adult *Tropidoclonion lineatum* was found under the same rock. Weather was sunny and warm. There had been rain in the area several times during the past few days. County record and a range extension to the north for North America (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Edition, expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.; Collins 1993, Amphibians and Reptiles in Kansas. Third Edition. Univ. Press Kansas, Lawrence. xx + 397 pp.; Miller 1982, Kansas Herp. Soc. Newsl. 28:5; Miller 1987, Investigation of Four Rare Snakes in South-Central Kansas. Final Report Kansas Dept. Wildlife & Parks, Pratt. 24 pp.).

Submitted by **DEREK MOELLER**, Washburn Rural High School, 5900 SW 61st Street, Topeka, Kansas 66619, USA, **ALLIE KOSSOY**, **WHITNEY HAMILTON**, and **LARRY L. MILLER**, Topeka Collegiate School, 2200 SW Eveningside Drive, Topeka, Kansas 66614, USA.

LYCOPHIDION TAYLORI. TANZANIA: Arusha Region (two localities): Samaria, near Kilimanjaro National Airport, 3°28'S, 37°05'E; Lolkisale, ca. 50 km SW Arusha city, 3°46'00"S, 36°24'00"E. January 1998. Joseph Beraducci. Zoological Museum, University of Copenhagen. Samaria ZMUC R602328; Lolkisale ZMUC R602084–85. Verified by Jens Bødtker Rasmussen (following Broadley and Hughes 1993, Herpetol. J. 3:8–18). First records from Tanzania. Previously known from Chad, Kenya, Senegal, and Somalia (Broadley and Hughes, *op. cit.*). The new record is situated ca. 750 km southwest of the closest record in southern Somalia (Broadley and Hughes, *op. cit.*).

Submitted by **PETER GRAVLUND**, The Zoological Museum, Vertebrate Department, Herpetological Section, University of Copenhagen, Universitetsparken 15, DK-2100, Copenhagen, Denmark.

NERODIA ERYTHROGASTER TRANSVERSA (Blotched Water Snake). USA: TEXAS: PRESIDIO CO: Big Bend Ranch State Park. Rio Grande between river miles 918 and 921. 2 October 1999. KU Color Slide 11727. Extends known range ca. 34 miles upstream of sightings (J. R. Dixon, pers. comm.) near the mouth of Santa Elena Canyon (RM 885), Big Bend National Park. An adult was observed and a juvenile captured (SVL = 260 mm, tail = 75 mm). Taken from riffle area at bend in the river. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). If found on the Mexican side of the river it would likely represent a new record for northern Chihuahua, Mexico (R. Conant, pers. comm.).

Submitted by **BRUCE L. CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87025, USA, **J. ERIC WALLACE**, 3414 West Sierra, Phoenix, Arizona 85029, USA, and **STEPHANIE C. BARTEL**, 907 Lockhart, Alpine, Texas 79832, USA.

NINIA HUDSONI (Amazon Coffee Snake). PERU: DEPARTAMENTO PASCO: Provincia Oxapampa: Alto Chinizo, ca. 14 km NW Pozuzo (10°07'S, 75°32'W), 1500 m elev. 19 December 1995. B. Vasques T. Collection of the Centro de Salud San Camilo Pozuzo (PE 1163) and photograph vouchers Natur-Museum und Forschungs-Institut Senckenberg (SMF-F 203–4). Verified by N. Carrillo de Espinoza. State record and northernmost locality for Peru.

Submitted by **EDGAR LEHR**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a. OXYBELIS FULGIDUS. VENEZUELA: ZULIA: Novito, Comunidad Yukpa del Cañon del Río Negro, Sierra de Perijá, Municipio Machiques de Perijá, 600 m. 10 October 1999. José Oviedo. Museo de Biología de la Universidad del Zulia, Maracaibo (MBLUZ R-452; 3 photographs B-R452 a–c, same individual). Verified by Luis Fernando Navarrete and Juan Carlos López Johnston. Previous authors (Roze 1966, La Taxonomía y Zoogeografía de los Ofidios de Venezuela. Ediciones de la Biblioteca, Universidad Central de Venezuela, Caracas; Lancini 1979, Serpientes de Venezuela. Armitano Ed. Caracas; Lancini and Kornacker 1986, Die Schlangen von Venezuela. Verlag Armitano, Caracas) mentioned the occurrence of this species only to the east and north of Venezuela. The present finding of *O. fulgidus* from Perijá region confirms its ocurrence in western Venezuela and extends the known range 800 km NW from previously published sites.

Submitted by **TITO BARROS** and **RAFAEL PIRELA**, Museo de Biología de la Universidad del Zulia (MBLUZ), Apartado Postal 526, Facultad de Ciencias, Departamento de Biología, Grano de Oro, Maracaibo, Estado Zulia, Venezuela.

OXYRHOPUS RHOMBIFER RHOMBIFER. BRAZIL: BAHIA: Lençóis (12°34'S 41°23'W). January–February 1999. M. A. de Freitas. Coleção Zoológica Gregório Bondar of the Centro de Pesquisas do Cacau/CEPLAC (CZGB 8853). Verified by Otávio Augusto Vuolo Marques. First record for state of Bahia and northeastern Brazil; subspecies was previously recorded from "provincia de Buenos Aires to east of Rio Paraná in Argentina and Uruguai; north to southern Minas Gerais and Rio de Janeiro, Brazil" (Peters and Orejas-Miranda 1970, Bull. U. S. Nat. Mus. 297: 235).

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz-UESC, Km 16 Rodovia Ilhéus-Itabuna, 45650-000, Ilhéus, Bahia, Brazil (e-mail: ajargolo@hotmail.com) and **MARCO ANTÔNIO DE FREITAS**, Universidade Estadual de Feira de Santana-UEFS, Avenida Universitária Km 03, BR 116, 44031-460, Feira de Santana, Bahia, Brazil (e-mail: sapirang@lognet.com.br).

PROSYMNA RUSPOLII KINIENSIS. TANZANIA: Arusha Region: Samaria, near Kilimanjaro National Airport, 3°28'S, 37°05'E. January 1998. Joseph Beraducci. University of Copenhagen (ZMUC R602327). Verified by Jens Bødtker Rasmussen (following Broadley 1980, Occas. Pap. Natl. Mus. Rhodesia B. Nat. Sci. 6[7]:481–556). First record from Tanzania. Previously known from Kenya (Broadley, *op. cit.*). This new record is situated ca. 175 km to the south of Sultan Hamud, the closest known locality in Kenya (Broadley, *op. cit.*).

Submitted by **PETER GRAVLUND**, The Zoological Museum, Vertebrate Department, Herpetological Section, University of Copenhagen, Universitetsparken 15, DK-2100, Copenhagen, Denmark.

RHINOBOTHRYUM LENTIGINOSUM. (Amazon Banded Snake). PERU: DEPARTAMENTO UCAYALI: Provincia Atalaya: Bolognesi (10°06'S, 73°49'W, 230 m elev.). 29 January 1999. E. Lehr. Museo de Historia Natural de San Marcos (MHNSM 20006). Verified by Javier Icochea. First record for state of Ucayali (Carrillo de Espinoza and Icochea 1995, Publ. Mus. Hist. Nat. UNMSM [A] 49:1-27).

Submitted by **EDGAR LEHR**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a. M., Germany (e-mail: elehr@sng.uni-frankfurt.de), and **CESAR AGUILAR**, Museo de Historia Natural, Departamento de Herpetologia, Universidad Nacional Mayor de San Marcos, Avenida Arenales 1256, Jesus Maria, Apartado 14-0434, Lima, Peru.

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga). USA: NEW MEXICO: HIDALGO CO: DOR, 1.6 km S (by road) Rodeo on Rt. 80. 18 July 1967. Manny Rubio. AMNH R107537. Verified by Harry W. Greene. County record (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp). The AMNH catalog lists the collection locality of this specimen as Cochise County, Arizona. However, the field tag on the specimen reads "Cochise Cty, Arizona & Hidalgo Cty, N.M." on one side and "1 mile south of Rodeo on 80 on Arizona-New Mexico border" on the other side (L. Ford, pers. comm.). The collector's (MR) field notes from this period indicate he regularly recorded distances to the nearest 0.1 mile. Traveling on Rt. 80, the southern edge of the town of Rodeo is 2.7 km (1.7 miles) NNE of the Arizona-New Mexico border. This places the specimen 1.1 km NNE of the Arizona-New Mexico border. Thus, we recommend reassignment of this specimen to Hidalgo County, New Mexico. Conversion of desert grassland to desert scrub has probably led to severe population decline or extirpation at this site, although the species persists in reasonable densities in a relictual tobosa grassland ca. 50 km to the southwest.

Submitted by **ANDREW T. HOLYCROSS**, Department of Biology, Arizona State University, Tempe, Arizona 85287-1501, USA, and **MANNY RUBIO**, 1665 DeFoor Avenue, Atlanta, Georgia 30318, USA.

SISTRURUS MILIARIUS MILIARIUS (Carolina Pigmy Rattlesnake). USA: GEORGIA: HALL CO: Cagle Mill Road, 2.6 km WSW Lula. 4 September 1995. Rob Wainberg. Georgia Museum of Natural History (GMNH 44320). Verified by M. E. McGhee. First county record and only the fourth documented Georgia record for this species outside of the Coastal Plain (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712).

Submitted by **ROB WAINBERG** and **CARLOS CAMP**, Biology Department, Piedmont College, Demorest, Georgia 30535, USA, and **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

SPILOTES PULLATUS (Tigra Cazadora, Tropical Rat Snake). VENEZUELA: ESTADO MERIDA: Municipio Antonio Pinto Salinas: 1 km N Santa Cruz de Mora (8°23'50"N, 71°38'30"W). 24 July 1985. Collector unknown, but catalogued data indicates "Proyecto Uribante-Caparo." Colección de Vertebrados de la Universidad de Los Andes (CVULA) IV-3878. Verified by R. Casado. ESTADO TRUJILLO: Municipio Rafael Rangel: Isnotú (9°22'N, 70°42'W). No date. J. L. Portillo. CVULA IV-5683. Verified by L. F. Esqueda. Santa Cruz de Mora is the westernmost locality for the species in the country, besides one record about 75 km to the west in the state of Zulia. Isnotú lies about 250 km SW of the northernmost known collecting localities in the state of Falcon.

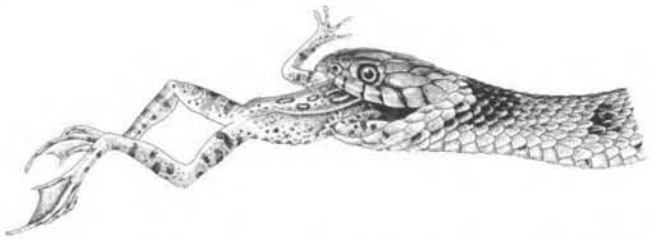
Both records constitute the first Venezuelan Andean documented records for this species (Roze 1966, La Taxonomia y Zoogeografia de los Ofidios de Venezuela: 217; Lancini 1986, Serpientes de Venezuela: 157; Lancini and Kornacker 1989, Die Schlangen von Venezuela: 229).

Submitted by **ENRIQUE LA MARCA**, Laboratorio de Biogeografía, Escuela de Geografía, Facultad de Ciencias Forestales y Ambientales, Universidad de Los Andes, Apartado Postal 116, Mérida 5101-A, Venezuela (e-mail: lamarca57@cantv.net), and **PASCUAL SORIANO**, Laboratorio de Ecología Animal-A, Departamento de Biología, Facultad de Ciencias, Universidad de Los Andes, Mérida, Venezuela (e-mail: pascual@ciens.ula.ve).

TELESCOPUS OBTUSUS (Large-eyed Cat Snake). TANZANIA: Arusha Region (two localities): Samaria, near Kilimanjaro International Airport, 3°28'S, 37°05'E; Lolkisale, ca. 50 km SW Arusha city, 3°46'00"S, 36°24'00"E. January 1998. Joseph Beraducci. Zoological Museum, University of Copenhagen (Samaria ZMUC R631350, R631352; Lolkisale ZMUC R631351). Verified by Jens Bødtker Rasmussen (following Broadley 1994, J.. African Zool. 108:[2]). First records from Tanzania. Previously known from Sudan, Ethiopia, Eritrea, Somalia, and Kenya. These new records are situated 350 km (Samaria) and 450 km (Lolkisale) to the west of the nearest record from Malindi, Kenya (Spawls 1978, J. East African Nat. Hist. Soc. Mus. 31:167).

Submitted by **PETER GRAVLUND**, The Zoological Museum, Vertebrate Department, Herpetological Section, University of Copenhagen, Universitetsparken 15, DK-2100, Copenhagen, Denmark.

THAMNOPHIS RADIX. (Plains Garter Snake). USA: KANSAS: GREENWOOD CO: NE 1/4 Sec. 22, T23S, R8E. 24 September 1999. Steven L. Adams, Kelly J. Irwin, and Joseph T. Collins. KU 289049. Verified by Steven L. Adams. DOR adult. New county record; most southeastern record in the state (Collins 1993, Amphibians and Reptiles in Kansas. Third ed. Univ. Press of Kansas, Lawrence. xx + 397 pp.).



Submitted by **KELLY J. IRWIN**, 1618 Davis Creek Road, Seneca, South Carolina 29678, USA (e-mail: lkirwin@clemson.edu) and **JOSEPH T. COLLINS**, Kansas Biological Survey, 2041 Constant Avenue, Lawrence, Kansas 66047, USA (e-mail: jcollins@ukans.edu).

TRIMORPHODON BISCUTATUS (Lyre Snake, Codorniz). MÉXICO: BAJA CALIFORNIA SUR: Sierra Vizcaíno, Rancho San José de Castro, 27°32'20.3"N, 114°28'18.7"W. 16 September 1999. Bradford D. Hollingsworth. Verified by L. Lee Grismer. LACM-PC 1333. A single juvenile (SVL = 212) was observed at night (2030 h). The most recent herpetofaunal account of the region (Grismer et al. 1994, Bull. So. California Acad. Sci. 93:45–80) reports *Trimorphodon biscutatus* from the Sierra Santa Clara, located 85 km to the SE.

The increasing number of workers in the field of tadpole biology will receive this long-awaited book with joy. Here, at last, is a specialist publication, written by a team of 14 international experts, that both provides a review of basic information, and indicates directions requiring further attention.

The book radiates the humor and easy-going nature of the editors, while remaining an accurate scientific publication. It is divided into 12 chapters, a useful glossary, 69 pages of literature cited, and indices of authors, subjects, and taxonomy. Each chapter is complete and could serve as a core text in a course on amphibian larvae, and will no doubt become required reading for these and related vertebrate biology courses.

The introductory chapter by Roy W. McDiarmid and Ronald Altig gives an overview of what a tadpole is, including the meaning of the word 'tadpole' (Middle English for 'the toad that seems all head'). It also reviews tadpoles as research subjects and provides a brief but thoughtful overview of research on tadpoles from the earliest description by Gesner through the modern contributions of North Americans, Europeans, and regional workers in other parts of the world.

Tadpole researchers use a variety of special methods that allow them to capture, preserve, and photograph their study organisms. Chapter 2 by McDiarmid and Altig starts with a review of staging – the sequence of appearance of developmental landmarks that enables comparisons to be made. They discuss problems and suggest methods of fixation and observation, including a range of methods for looking at mouthparts. They offer a number of useful suggestions for illustrating tadpoles, both preserved and live, and conclude with a discussion on rearing the larvae. A table of ecomorphological diversity summarizes much of what is known.

The third chapter, on body plan development and morphology by Altig and McDiarmid, is significant as it proposes a standardized terminology. Presently, workers on different continents, or publishing in different languages, use a variety of terms. This book should rapidly become the standard work on tadpoles, and I believe that the authors will succeed in their desire to simplify the confusing and often contradictory terms available. They go on to discuss the morphology and ontogeny of the major tadpole components. The micrographs and useful explanatory diagrams will enable even a beginner to appreciate the subtle differences in, for example, the position of the vent tube relative to the fin. I was somewhat disconcerted to find that the tadpoles were drawn inverted, with the lower fin at the top of the illustration (Fig 3.5). However, I guess this was Altig and McDiarmid's way of testing the reader! The discussion of the oral apparatus terminology is critical, as this is an area of little agreement in the literature. They present numerous examples to illustrate the discussion and this chapter will surely serve as a baseline for future tadpole descriptions.

David Cannatella's fourth chapter on cranial and axial musculoskeletal architecture starts with a discussion of the early developmental morphology of tadpoles. It covers the skeleton and muscles of the chondrocranium, jaws, hyobranchium, and trunk. The information was derived from taxa as diverse as *Rana temporaria* and *Xenopus laevis*, reflecting the patchy coverage of detailed studies. A table summarizing the literature on tadpole chondrocrania, muscles, and gill apparatus is provided, and will be useful as a starting point for those entering this field. The detailed, well-labeled drawings, of both skeleton and muscles, will be of immense help for students. After the anatomy is discussed, Cannatella moves on to explore how the elements are involved in locomotion, gill irrigation, and jaw movement. The interplay between feeding and gill irrigation is discussed and illustrated with simple diagrams. All those interested in tadpoles will be aware of Orton's four tadpole types. The chapter concludes with an examination of the relationships of these types in terms of previous misinterpretation of larval anatomy and function, in a phylogenetic context. Cannatella suggests that retaining Orton's categories will only hinder our understanding, as the types are not homogenous.

Chapter 5, on the anatomy of the viscera and endocrines, is written by Bruno Viertel and Susanne Richter. Like the previous chapter, the information is based on studies from only a few genera, typically *Rana*, *Bufo,* and *Xenopus*. The authors carefully elaborate the origins, anatomy, function, and where known, the changes at metamorphosis. The circulatory, respiratory, digestive, urogenital, and endocrine systems are discussed. These are explained using clear drawings and micrographs.

Michael J. Lannoo considers the tadpole nervous system in chapter 6. This addresses the questions of how tadpole nervous systems function, what changes at metamorphosis, and which tissues developed in the tadpole are later used in the adult. Lannoo remarks on the variation known in the few taxa that have been studied so far. Detailed descriptions of the spinal cord, brain, and sensory systems are accompanied by excellent drawings. The literature is widely reviewed, and this chapter, like the others in the book, will serve as a useful synthesis. The summary emphasizes that some parts of the tadpole nervous system function only in the tadpole, while other parts are important only in the adult. Paradoxically, some elements are completely changed at metamorphosis, while the majority of neurons do not change at this time.

Although the 'typical' tadpole is a free-swimming, feeding organism, the next chapter on endotrophic anurans by Giselle Thibaudeau and Ronald Altig sets out to explore and document the structure and function of endotrophs—those larvae that obtain their food entirely from parental sources, frequently vitellogenic yolk. Thibaudeau and Altig start by comparing the development of endotrophs, followed by a discussion based on the best known example *Eleutherodactylus coqui*. Anyone who has attempted to follow the development of direct-developing species will be amazed at the volume of information presented, both on morphology and physiology. Because endotrophs are not restricted to open

water, they are able to occupy a range of special habitats. The evolution of endotrophy is considered in a carefully researched section. Endotrophy is compared in many of the lineages in which it is known, concluding with speculation on the genetic mechanisms that might have led to the evolution of direct development.

Frogs have served as model organisms in the study of vertebrate physiology for over a century. Tadpole physiology is well reviewed in chapter 8 by Gordon R. Ultsch, David F. Bradford, and Joseph Freda. The importance of respiration in an aquatic tadpole that later breathes air as an adult is reviewed in terms of hemoglobin function, oxygen uptake, gas exchange, carbon dioxide elimination, and acid-base balance. Gas exchange turns out to be complex in tadpoles, as they may have several sites, like gills, skin, and lungs, where it occurs. Tadpoles may live in habitats from those covered in ice, to those at more than 40°C in the tropics. Temperature tolerance, behavioral thermoregulation, and a host of related topics are reviewed. Many of the interesting examples presented encourage the reader to consult the list of cited literature. Some species are gregarious, and the relationship of thermoregulation and aggregation behavior is reviewed. Tadpole osmoregulation is incompletely known, but nevertheless the current state of knowledge is presented and the reader is pointed to questions that still need to be answered.

Tadpoles do not concern themselves with sex. Chapter 9 by Karin vS. Hoff, Andrew R. Blaustein, Roy W. McDiarmid, and Ronald Altig covers other behaviors associated with development, growth, and survival to metamorphosis. Tadpole behavior is not well studied—in fact many tadpoles in some parts of the world have never been seen. This chapter reviews the behaviors associated with general maintenance (feeding, respiration, thermoregulation, and locomotion), dispersion and within-species interactions (habitat selection, social interactions, kin recognition, and kin association), and sensory abilities and learning (vision, cutaneous senses, and chemical communication). In this very detailed chapter the authors review a wide range of studies and present a balanced interpretation. One example will suffice: The confusion in the literature from 1929 when Vincent Wager speculated on the maternal behavior of the African *Hemisus marmoratus*, has been perpetuated in every review until recently. Finally a correction published by Van Dijk in 1985, followed by field observations by M.-O. Rödel and others in West Africa put the matter to rest. This mess of inaccuracies is carefully documented and set straight.

Ross A. Alford contributed chapter 10 on tadpole ecology. This reviews the literature concerning tadpole habitats and communities (general features, resource use, and effect on resources), growth, development and survival, interactions with predators and competitors, and composition and ecology of species assemblages (density and resource use, field studies, effects of environmental uncertainty). The extensive experimental literature is reviewed and a balanced synthesis results that will be valuable to anyone entering the field of amphibian larval ecology. Tadpoles are widely used as model systems as they can be easily manipulated, and Alford concludes with a discussion of areas in need of further investigation.

Most aspects of the tadpole are covered in some detail in previous chapters, and Reid N. Harris is concerned in chapter 11 with the evolution of the complex anuran life cycle. Why have a tadpole stage? Harris approaches this by looking at the tadpole stage as an adaptation, examining growth and metamorphosis, and reviewing what is known of the ecological genetics of larval traits. The origin and maintenance of a complex life cycle are carefully reviewed. Harris argues that the tadpole is specialized for growth, but notes that several areas require further work.

The final chapter on diversity, another by Altig and McDiarmid, offers a list of pertinent literature with an indication of the presence of keys, a list of previously misidentified tadpoles in the literature, and a condensed summary of all known tadpoles. This consists of abbreviated information on numbers of taxa, geographic range, ecomorphological guild, mouthpart details, morphology, and a drawing of a representative morphotype. This summary will surely encourage new students into the study of tadpole diversity.

The last 100 or so pages of the book are taken up by a glossary, literature list, and indices. The glossary explains terminology and also indicates alternative accepted and unaccepted terms. This book will be a valuable addition to the library of everyone interested in amphibians. As tadpoles are useful model systems, I am sure it will become part of the core literature for all vertebrate biologists.

The book starts with a quote by Kermit the Frog, and I use this opportunity to mis-quote Kermit in conclusion: "When I was a young tadpole growing up back in the swamps, I never imagined that I would one day be discussed by such an outstanding group of scholars."

e-mail: rdesa@richmond.edu

As the title indicates, this well-illustrated (115 photographs and 76 illustrations) book summarizes the current knowledge about the natural history of the 16 species of *Eleutherodactylus* inhabiting Puerto Rico. The book consists of eight chapters (including the epilogue) and it is clearly stated that it was written to serve both the scientific community and the nonspecialist reader. The goal of bridging these two audiences is ambitious and usually difficult; however, the book has probably accomplished this goal. The technical reader, i.e., students and professional herpetologists, will find a good summary of data and enough information to continue reading with interest. On the other hand, the nonspecialist reader will not be overwhelmed with technicalities and terminology beyond their reach. Indeed, it is the clear writing for a general audience that gives this book strength; furthermore, this will make the book a good general reference. The latter is important because this anticipated wide use could influence, for years to come, the general public and their approach to the island's environmental and conservation problems.

Chapter 1 serves as an introduction not only to the "world of coqui frogs" but to amphibians in general. The next three chapters represent species accounts for each of the Puerto Rican species of *Eleutherodactylus*. These accounts are most extensive for two species, *E. coqui* (Common Coqui, chapter 2) and *E. cooki* (Guajon or Puerto Rican Demon, chapter 3), the remaining 14 species of *Eleutherodactylus* are included in chapter 4. The more extensive focus on *E. coqui* and *E. cooki* probably results from the author's personal experience and the fact that more information has been accumulated over the years for these two taxa. However, all species accounts include a species description providing details of size, coloration, and morphology. References are given to additional illustrations of these species, and similar species are noted. Following the species descriptions are brief sections on distribution (with clearly-plotted maps) and natural history. The latter consists of data on habitat, behavior, reproduction, call characteristics, egg clutches, development, and other topics. The information on natural history is not uniform across taxa due to a lack of relevant data for several species. The gaps evident from these accounts could serve to guide students in the directions needed to further our knowledge of the basic biology of these species. The penultimate section includes recommendations on conservation and a summary of the current legal status of each species. I found this to be a unique and valuable contribution to the book. In particular it is very informative with respect to observed fluctuations in species populations, past conservation efforts, and responses to these efforts (mostly none!). Each species account ends with a brief section on systematics and nomenclatural history that will be of interest to the technical reader.

The remaining half of the book (chapters 5–7) is an overview of the ongoing research efforts to understand the biology of *Eleutherodactylus* species in Puerto Rico. Chapters 5 and 6, especially, present a variety of information collected by the author's research team over the last decade on species ecology, behavior, demography, conservation, and the effect of natural events (such as Hurricane Hugo) on natural populations. Although the data in these chapters may be of more interest to professional herpetologists and conservationists, it is presented clearly and should also be accessible to the non-specialist reader.

The final chapter, the epilogue, focuses on presenting the nonspecialist reader with an overview of the current environmental crisis and the responsibility that humans have in this crisis. This effort to educate the public is important and should never be dismissed or ignored.

A shortfall of the book is the lack of dichotomous keys to identify the species of *Eleutherodacytlus*. We are told at the beginning that this lack is a conscious effort to avoid the collection and handling of *Eleutherodactylus* for non-scientific or educational purposes. However, dichotomous keys would be a useful addition for the professional audience. Furthermore, if the idea is to protect critical populations and species, then I see a much greater danger in providing distributions maps with detailed plotting of previous collections.

In summary, the book is a welcome addition that brings together a good mixture of new data on the biology of Puerto Rican *Eleutherodactylus* and summary accounts of the status of each species. The book will be an excellent addition to the library of any professional or non-specialist reader interested in Puerto Rican frogs and natural history.

The Amphibians and Reptiles of Nicaragua: A Distributional Checklist with Keys, by Gunther Köhler. 1999. Courier Forschungsinstitut Senckenberg 213, 121 pp, with 10 plates. (available from Senckenbergische Natuforschende Gesellschaft, Schriftentausch, Senckenberganlage 25, D-6025 Frankfut am Main, Germany). Softcover, DM 55 (approx. US $29.00). ISBN 3-929907-55-0.

JOSEPH R. MENDELSON III
Department of Biology, Utah State University, Logan, Utah 84322-5305, USA
e-mail: sapo@biology.usu.edu

Nicaragua is the largest country in Central America and has the most poorly documented herpetofauna in the region. Although distributional records for some species in the country have appeared in taxon-specific monographs (e.g., Duellman 1970; Myers 1974), the only reasonably comprehensive work for this country is Villa's (1972a) book on amphibians—which is difficult to locate. Consequently, for a country as poorly studied as Nicaragua, any work such as this new book by Gunther Köhler is likely to be of significance to researchers with interests in Middle America.

This book contains brief species accounts for 227 species of amphibians and reptiles known (or suspected) to occur in the country. Each account contains basic taxonomic information, a partial synonymy, general distributional information, and locality data taken from the literature and from specimens examined by the author. Subspecies are not considered in this work, but do appear in the taxonomic synonymies. Keys are presented for the genera in each order, and for each genus with more than one species occurring in Nicaragua. Dot maps are presented for most species and Köhler has carefully used different symbols to indicate locality records based on museum specimens, sight records, and unverified records taken from the literature. Numerous line drawings are used to illustrate specific morphological features mentioned in the keys. The plates contain photographs of general habitat types and 54 species photographed in life. A brief Introduction includes a checklist and list of taxa with type localities in Nicaragua.

The book is generally well typeset, organized, and easy to use. One apparent typesetting error (p. 71) appears to present a species account for the subspecies *Elaphe flavirufa pardalina,* when in fact it is simply an entry in the synonymy. The random taxonomic coverage of species illustrated in photographs suggests that the author used simply whatever was available. Nevertheless, the quality of the photographs ranges from good to excellent. The line drawings generally do an adequate job of illustrating the morphological details mentioned in the keys, but those for the squamate species are of generally much higher quality than those for the amphibians. At least one line drawing (fig. 104, showing details of squamation of *Geophis* spp.) is not referenced in the text and the details shown in figure do not appear in any key; it is not clear why this figure was included. My copy included a few small areas of poor print reproduction, but none so large that any passage was unusable. The maps are clear and well reproduced, but it would have been quite useful to include a map in the Introduction showing the names of the political departments. The writing is generally

good, with few instances of poor grammar or punctuation. One misspelling had "Slovinski" instead of "Slowinski" and one lapsus had "Atlántida Norte" instead of "Atlántico Norte." In all cases, however, the sense of the text is clear and overall the book is quite readable.

In any work involving taxonomy of so many species, the author has difficult choices to make regarding which taxonomic treatments to follow—knowing full well that everyone cannot be pleased. Nevertheless, the author owes the reader a few statements regarding the criteria used in selecting the taxonomy presented; Köhler does not present any such criteria. Consequently we see relatively uninformative, if traditional, taxa such as Iguanidae rather than Phrynosomatidae, Polychrotidae, etc.... used throughout the book. Generic allocations are inconsistent with respect to recent literature, as we see *Celestus* retained instead *Diploglossus,* and *Pliocercus* retained in favor over *Urotheca,* while other recent generic reallocations (e.g., *Cerrophidion* and *Atropoides*) have been adopted. The dipsadine taxon *sartorii* is referred inconsistently to *Sibon* and *Tropidodipsas* in the key, map, map legend, and species account.

The bulk of Köhler's work here—and potentially its most valuable contribution—is found in the checklist and distributional data presented in the maps. However, while Köhler acknowledges eight major museums for access to specimens and records in their collection, we see that nearly every museum record indicated here came from only two collections (The University of Kansas and the Senckenberg Museum). Consequently, I found gaps in distributional data representing specimens I know to exist in, for example, the American Museum of Natural History. Simply put, a week of work in a major herpetological collection will render this book outdated. This is regrettable because it is my opinion that a work such as this should summarize **all** of the existing data, in hopes that it will eventually become outdated as new information is generated by field work. Even more distressing is that a number of records from the scant literature on the Nicaraguan fauna have been apparently overlooked. For example, *Agalychnis callidryas* and *Hyla phlebodes* have both been reported from the Corn Islands (Barbour and Loveridge 1929; Villa 1972b) as have *Micrurus nigrocinctus* and *Elaphe flavirufa* (Dowling 1952; Roze 1967; Villa 1972c); the latter three species are represented by specimens at AMNH. The paper by Roze was cited by Köhler, but those by Barbour and Loveridge, Villa, and Dowling were not referenced in this book.

In the Introduction, Köhler discusses five species that are likely to occur in Nicaragua but have yet to be found there (e.g., *Anotheca spinosa)*; these species are rightfully included in the keys and species accounts. Another ten species, that have appeared on previous checklists for the country, but for which voucher specimens are lacking, are excluded because they are deemed "less likely to be found in Nicaragua." However, the rationale for excluding these latter species is only given in three cases; the remainder are dismissed without comment. Despite these special-case species, several others appear in species accounts for which there evidently are no records from the country (e.g., *Anomolepis mexicanus, Nothopsis rugosus, Pelamis platurus,* and all of the sea turtles). It is not clear why these were treated differently than the other species for which there are no records. Köhler has included these in the Nicaraguan fauna without any apparent data, justification, or commentary. Another species, *Sibon longifrenis,* also lacks any records from Nicaragua, but is included based on reasonable inference from specimens from Costa Rica. In any case, Köhler has been inconsistent with regards to his criteria for including or excluding species of questionable status for the country.

A particularly disturbing aspect of this book is that information from the literature has been presented without properly crediting the original source. In the Introduction Köhler states that the "....keys were modified from important works on the neotropical herpetofauna such as..." and he goes on to list ten citations. Major monographs by Myers (1974) and Duellman (1970) do not appear in this list even though it is clear that information from these works was used in preparing the keys. For example, Köhler's key to species of *Rhadinaea* contains data from scale counts that were clearly taken directly from Tables 6, 11, and 16 in Myers (1974). Each key in this book should have been clearly labeled as having been modified from the specific source. It is not appropriate to simply give broadscale—and incomplete—credit to "major works in neotropical herpetology." Other examples of this problem appear in each species account, where information regarding the geographic distribution of each species appears to have been taken in many cases directly from Peters et al. (1986), but without credit to these authors. In other cases, the original, uncredited source is not at all evident. For example, Köhler stated that *Eleutherodactylus bransfordi* ranges from "Southeastern Nicaragua to central Panama." This is rather detailed information, yet the source of this information is not credited. Because Köhler did not examine any specimens of this species, we cannot attribute this information to his own efforts.

I detected no real errors in this work, but I did find a number of omissions with respect to information that exists in museums and in the literature. Nonetheless, this book does represent a nicely prepared, conservative summary of information regarding the herpetofauna of Nicaragua and therefore will likely be of great use to researchers working in that region.

Erratum

In HR 30(3):162, the note by Bernarde and Machado contains two errors. *Hyla faber* builds nests in small basins without foam, not in "foam nests" as indicated. The correct spelling of the first author's name is Paulo Sérgio Bernarde. We regret the errors.

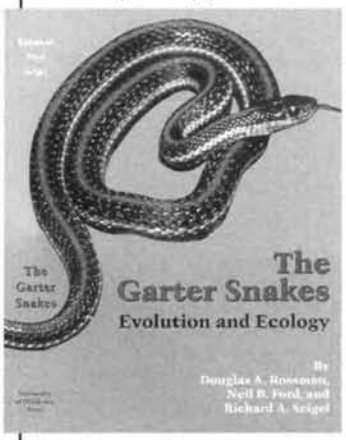
Know Your Animals Well

Amphibians and Reptiles of Northern Guatemala, the Yucatán, and Belize

By Jonathan A. Campbell

Ranging from the enormous and potentially dangerous to the tiny and secretive, about 160 species are illustrated and profiled in the first field guide to the reptiles and amphibians of this diverse region of Central America. This guide is designed for scientists, tourists and armchair travelers. It includes frogs, toads, salamanders, caecilians, turtles, lizards, crocodiles and snakes; notes on where to look for the animals; folklore and adventures; four decades of Campbell's own observations; and English and Spanish identification keys.

400 pages, **176 color and 11 b&w illustrations**, maps, glossary, 7 × 10.
$100.00 Hardcover
$29.95 Paper



The Garter Snakes

Evolution and Ecology

By Douglas A. Rossman, Neil B. Ford, and Richard A. Seigel

All 30 recognized species of garter snakes are examined in this first comprehensive review of the genus Thamnophis in nearly ninety years. The book includes a modern key to all species and for each species, color plates and summaries of the systematics and natural history. It details each species' habitat, distribution, preferred diet, reproductive and population biologies, and captive maintenance, concluding with a discussion of conservation concerns. Written by the world's leading authorities, this appealing book will be highly useful not only to herpetologists but also to conservationists, ecologists, pet owners, and others interested in natural history.

"Garter snakes! And more garter snakes! . . . This keystone coverage . . . will set the herpetological standard for works of this type."—**J. Whitfield Gibbons**, University of Georgia

268 pages, **88 color and 31 b&w illustrations**, 28 maps, glossary, index, 7 × 10. **$65.00 Hardcover**

Animal Behavior

General Editor: Timothy Halliday

How do birds navigate? Why do bees dance? How do sea anemones fight? Written by a team of international experts, this beautiful book is packed with examples of the activities of all types of animals—mammals, birds, reptiles, insects and fish—as they find shelter and food, attract a mate, care for their young, defend themselves, navigate, and survive the many challenges of life. The relationships animals have with other animals—food, friend, or foe—are a major element in their activities. Animals' behavior is important to the earth's ecological balance, and thus a key to the vitality of the planet.

144 pages, **251 color plates, 22 b&w illustrations**, 8½ × 11.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA.

All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700		$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 700	$270

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2000 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@slu.edu.

Future Annual Meetings

2000 — Universidad Autónoma de Baja California Sur, La Paz, BCS, México, 14–21 June 2000 (Carlos Villavicencio, Chair).
2001 — Indiana University/Purdue University, Indianapolis, Indiana, USA, 26–30 July 2001

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
2000 ANNUAL MEETING

together with

AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS

and

THE HERPETOLOGISTS' LEAGUE

14 – 21 June 2000
Universidad Autónoma de Baja California Sur, La Paz, BCS, México

La Universidad Autónoma de Baja California Sur is located in La Paz, BCS, in the southern part of the Peninsula, in the Gulf of California. Founded in 1535, La Paz is a small and quiet city, known for good drinks and food services.

Keynote Address: "FROGS, FOSSILS AND PHYLOGENY: A PERSPECTIVE ON THE LAST 140 MILLION YEARS AND PROSPECTUS FOR THE FUTURE," by Linda Trueb, The Herpetologists' League Distinguished Herpetologist for 2000 (The University of Kansas).

Symposium: "ECOLOGY AND EVOLUTION IN THE TROPICS: ESSAYS IN TRIBUTE TO JAY SAVAGE." *Organizers:* Maureen A. Donnelly, Florida International University (donnelly@fiu.edu); Brian I. Crother, Southeastern Louisiana University (bcrother@selu.edu); Craig Guyer, Auburn University (cguyer@acesag.auburn.edu); Marvalee H. Wake, University of California, Berkeley (mhwake@garnet.berkeley.edu); and Mary E. White, Southeastern Louisiana University (mwhite@selu.edu).

Symposium: "PARTNERS FOR AMPHIBIAN AND REPTILE CONSERVATION." *Organizers:* Henry Mushinsky, Department of Biology. University of South Florida. Tampa, Florida 33620-5150, USA; tel. 813-974-5218, fax 813-974-3263: (mushinsk@chumal.cas.usf.edu). Laura Herbeck, North Central Research Station, U.S. Forest Service, 202 Natural Resource Building, University of Missouri, Columbia, Missouri 65211, USA; tel. 573-875-5341 ext. 227. Cynthia Carey. Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA; tel. 303-492-6014.

Symposium: "THE NATURAL HISTORY AND EVOLUTION OF THE HERPETOFAUNA OF SOUTHERN CALIFORNIA AND BAJA CALIFORNIA." *Organizers:* Robert Fisher, USGS-Western Ecological Research Center, SDSU Field Stations, Department of Biology, San Diego State University, San Diego, California 92182-4614, USA; tel. 619-594-8026, fax 619-594-2035 (rfisher@sunstroke.sdsu.edu) and Robert Lovich, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA and Department of Biology, San Diego State University, San Diego, California 92182-4614, USA; (rlovich@sciences.sdsu.edu).

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day throughout the conference.

Meeting Site: SSAR, HL and CAH will meet in the Hotel Araiza Inn Palmira; palmira@balandra.uabcs.mx; tel. 121-6200, fax: 121-6227; International Reservations 1-800-9-ARAIZA, National Reservations 01-800-71-68-777. Other recommended close hotels are: Marina, El Moro, and La Concha (contact details and locational map are provided in the official meeting announcement).

Travel Arrangements: Everyone will need to make their own hotel reservation. The recommended airport is La Paz, but also you can fly into Los Cabos (220 km south), and then rent a car.

Student Travel Award: Ten travel grants of US $200 each will be available for SSAR student members. Refer to page 197 of the December 1999 issue of *HR* for details.

Student Paper Award: Henri Seibert prizes (US $200 each) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. Refer to the official Meeting Announcement for details.

Social Activities: General Reception at the Municipal Dock, SSAR Auction, SSAR Herp Silent Auction, Beach Barbecue, Graduate Student Reception, and ASIH Banquet.

Multimedia Events: Special Herpetologists' League Illustrated Lecture: "THE AMPHIBIANS AND REPTILES OF BAJA CALIFORNIA AND THE SEA OF CORTÉS," by Lee Grismer. SSAR Presidential Slide Show (presenters and titles to be announced).

Field Trips: Will be arranged to nearby desert areas and islands.

Costs: Preregistration US $185 regular, US $95 student, US $95 accompanying person. After March 15, 2000, costs are US $245, US $135 student.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Further Details: Meeting Announcement and Call for Papers was mailed to all Canadian, U.S., and Mexican members of the participating societies in January 2000. Overseas members wishing to receive this information may do so by contacting Carlos Villavicencio Garayzar, Local Chair, Universidad Autonoma de Baja California Sur. A.P.19-B. La Paz, B.C.S., México. CP23080; (cvilla@calafia.uabcs.mx & ASIH@calafia.uabcs.mx), Tel. & fax: 011-52-1-128-0775. Please visit the meeting web site at www.uabcs.mx/asih for additional and updated information.

About Our Cover: *Lachesis stenophrys*

From practically the earliest times that Europeans traveled to Latin America, one of the snakes that galvanized their attention, drawing forth lurid tales of destruction and agonizing death, was the bushmaster (among many, see Bancroft 1769. An Essay on the Natural History of Guiana. T. Becket and P. A. DeHondt, London. 402 pp.). Even recently, articles misrepresenting these imposing reptiles have been published. Bushmasters are nothing if not inspiring.

Despite obvious variation, for years this snake, the greatest of the pitvipers and largest of all venomous snakes in the Western Hemisphere, was regarded as a single species, *Lachesis muta* (Serpentes: Viperidae), with three races: *muta*, *stenophrys*, *rhombeata*, and (later) *melanocephala*. Its distribution, collectively, comprised lower Central America from Nicaragua south through Costa Rica, Panama, Trinidad, and throughout northern South America as far south as Bolivia. But tectonic and glacial events conspired to repeatedly separate and rejoin the primeval forests in which bushmasters make their homes, and because of the ensuing variation among the isolated populations (not to mention the advent of sophisticated techniques for analysis), we now recognize three species of these snakes: *L. stenophrys*, *L. melanocephala*, and *L. muta* (Zamudio and Greene 1997. Biol. J. Linn. Soc. 62:421–442). The last species is wide-ranging and comprises two or more somewhat distinctive races.

The Eastern Bushmaster, *Lachesis muta rhombeata*, is probably endangered, and restricted to the rapidly diminishing rainforests of Brazil's Atlantic Coast, from Ceará south to Rio de Janeiro. The Common Bushmaster, *Lachesis muta muta*, is found throughout the Amazon and Orinocoan Basins. The Black-headed Bushmaster, *Lachesis melanocephala*, is endemic to southwest Costa Rica; its population merits monitoring owing to reduced habitat. The Western Bushmaster, *Lachesis stenophrys*, is distributed from Nicaragua south through Costa Rica and Panama and including adjacent Colombia and Ecuador, east of the Andes mountains (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York. 425 pp.).

Bushmasters are magnificent and misunderstood reptiles. They naturally exist in low densities and specimens are seldom encountered in anything but primary rainforest. Owing to their largely sedentary lifestyle, finding a bushmaster is not an everyday event, and most local inhabitants never see them. Bushmasters are large, but, like most aspects of their behavior, their size has been exaggerated, and literature references to four meters or more in length remain unsubstantiated. However, large male bushmasters exceeding three meters are known. Bushmasters are among the few egg-laying pitviper species and they are unique in possessing a tail terminating in a scaly spine.

Usually torpid by day, bushmasters can be alert and formidable when moving from one location to another at night or during breeding season, when males engage in ritual combat and are often awake during daylight hours. So, while most brushes with *Lachesis* involve sluggish animals, sometimes their behavior is quite the contrary. Thus, true stories abound of naive or careless persons free-handling bushmasters with impunity. The occasional story of seemingly unprovoked attack, often with grave consequences, can also be true. It is rare for humans to sustain bites from these snakes, but they are usually serious medical emergencies when they occur because of the relatively long fangs, the potentially large amount of venom injected, and the location of the bite. Many of the vernacular names by which bushmasters are known refer to extreme lethality (ox-killer; silent death in the night, etc.), rugose appearance (pineapple snake, warty snake), or the odd tail (mute rattlesnake).

The specimen depicted on our cover is a 2.2 meter-long, male Western Bushmaster, *Lachesis stenophrys*. It was found in montane rainforest and photographed by **William W. Lamar** in Limón Province, Costa Rica. Lamar used a log-mounted Pentax LX camera, Vivitar Series 1 105mm f/2.5 macro lens, and Fujichrome Provia film. Exposure was at f/22 under natural light during a rainstorm. Lamar, who has worked with bushmasters in six countries, says that they are as misunderstood, and as deserving of protection, as Great White Sharks. Bill resides in Tyler, Texas, but spends much of his time assisting with Latin American wildlife documentaries and conducting natural history tours to Peru, Costa Rica, Ecuador, and Venezuela for **GreenTracks, Inc**. Bill is shown here playing with a spring-loaded model anaconda during filming for a BBC segment in Venezuela.

Separation and imaging of Lamar's photograph is the work of **Jim Bridges** of **Herpeto, Inc.**, Hollywood, Florida.

SSAR BUSINESS

Notice to La Paz 2000 Meeting Attendees

If you have experienced difficulty reaching reservations help, know that you may contact Rebeca Preciado Gregoire, Reservations Department, Araiza Inn Palmira: palmira@balandra.uabcs.mx for reservations. In the SUBJECT line, put: "For Rebeca Preciado Gregoire."

HR Staff Changes

Travis Ryan (Savannah River Lab) is the new Section Editor for Legislation & Conservation, replacing **Jeff Demuth**. **Winston Card** (Dallas Zoo) takes over as Section Editor for Herpetological Husbandry, replacing **Ardell Mitchell**, who has resigned following a nine-year tenure as section editor. **Adam Summers** (Museum of Vertebrate Zoology, UC Berkeley) has joined the ranks of Associate Editors. **Jennifer Garrison** (University of Kansas) has replaced **Anne Maglia** as a Section Editor for Current Research. On behalf of the SSAR Board, the editors thank Jeff, Ardell, and Anne for outstanding service to their colleagues and wish them well in future endeavors.

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (to serve as President for a two-year term starting in 2001): ..... *David Green*
Secretary ..... *John Matter (unopposed).*
Treasurer ..... *Robert Aldridge (unopposed).*
For three-year term on Board of Directors:
..... *Karen Lips and Alvin Braswell.*

Amendment to Constitution* ..... *Approved*

*Provides for a two-year term of office for all SSAR Board positions. Refer to HR 30(1):2 for details.

NEWSNOTES

Highlands Biological Station Courses for 2000

Biology of Plethodontid Salamanders (22 May–3 June)—The southern Appalachians are renowned for their diverse salamander fauna. This course acquaints students with plethodontid salamanders and shows how studies of these animals have enhanced our understanding of a series of major evolutionary and ecological topics. This is a lecture, field, and laboratory course that will include discussions of original research papers. The instructor will be Stephen G. Tilley.

Conservation Biology of Amphibians (5–17 June)—This course is designed for advanced students and wildlife professionals interested in understanding the basic processes regulating natural amphibian populations and communities, as well as contemporary problems associated with the conservation of amphibian diversity. Students will participate in a class field project on the effects of forest management practices on woodland salamanders and sharpen their communication skills through individual presentations on selected topics. The instructor will be Raymond D. Semlitsch.

Three semester hours credit at the advanced undergraduate level are available for each course through either Western Carolina University or the University of North Carolina at Chapel Hill. For more information contact: *Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA. Tel. (828) 526-2602, fax (828) 526-2797, e-mail: hibio@wcu.edu, Internet: www.wcu.edu/hibio.*

Museum of Vertebrate Zoology Herpetological Collection Online

The collection of amphibians and reptiles in the Museum of Vertebrate Zoology (MVZ), University of California, Berkeley contains approximately 230,000 catalogued specimens (web site: http://www.mip.berkeley.edu/mvz/ and click on Collections). Of these, 123 specimens have been designated holotypes, 1713 are paratypes, two are syntypes, and three are neotypes. Most specimens are fluid-preserved, but the collection also contains skeletal preparations, sets of amphibian eggs and larvae, and several thousand specimen skeletons are cleared and stained. Other special collections include pineal organs, 800 sectioned heads, a series of dried anuran skins from California and Argentina, and stomach contents that have been removed from more than 3000 predatory reptiles. While the collection contains representatives from every continent, it is unsurpassed in its holdings from western North America and has important series from Latin America and from eastern and central Asia. Taxonomically, it contains representatives of every amphibian and reptile order. Approximately 82% of families and 62% of extant genera are represented.

All MVZ specimen data are now available online at http://elib.CS.Berkeley.EDU/mvz/. For questions please contact: *Museum of Vertebrate Zoology, 3101 Valley Life Sciences Building, University of California, Berkeley, California 94720-3160, USA (tel. 510-642-3567, fax 510-643-8238, e-mail: mvzquery@uclink.berkeley.edu).*

Request for Mexican Herp Literature

Almost two years ago I was asked by Dr. Hobart M. Smith to take over the continuation of the *Synopsis of the Herpetofauna of Mexico* series which consists of seven volumes to date. The literature search for volume seven ended in 1991. I have been collecting citations since then and scanning them for herpetological names from the generic level to the subspecific (if any). My search of the literature from 1991 to the present, with Dr. Smith's help, has yielded 3000+ citations from the scientific and lay literature. "Gray" literature is included when available.

I am requesting the assistance of the herpetological community to send me reprints (originals or photocopies) of papers dealing with the Mexican herpetofauna from 1991 through 1999 and for any references known to have been overlooked in previous volumes so that they may be included. DO NOT send items from the following: *Am. Mus. Novitates, Bol. Soc. Herpetol. Mex., Bull. Am. Mus. Nat. Hist., Bull. Chicago Herpetol. Soc., Caribbean J. Sci., Chelonian Conserv. Biol., Copeia, Herpetologica, Herpetol. Monogr., Herpetol. Rev., HISS, J. Herpetol., Int. Wildl., Marine Turtle Newsl., Nat. Geog. Mag., Nat'l Wildlife, Proc. Biol. Soc. Washington, Proc. Louisiana Acad. Sci., Reptile & Amphibian Hobbyist, Reptile & Amphibian Mag., Reptiles, Smithsonian, Sonoran Herpetologist, Trans. Kansas Acad. Sci., Southwest. Nat., The Vivarium,* and *Tulane Stud. Zool. Bot.*, as I receive these regularly. If any books are involved please provide the bibliographic citation; if I don't have it I will possibly request that it be scanned for names. Please send reprints or direct inquiries to: *Ernest A. Liner, 310 Malibou Boulevard, Houma, Louisiana, USA 70364-2598; e-mail: eliner@mobiletel.com.*

Internet News List of St. Petersburg State University

An e-mail subscription list has been organized under the auspices of the Department of Vertebrate Zoology of St. Petersburg State University (Russia) and the Department of Terrestrial Vertebrates of the Zoological Institute (St.-Petersburg). The List also contains information about current issues of the *Russian Journal of Herpetology* (www.folium.ru/rjh), new books and periodicals in the field, expeditions, job opportunities, grants, fellowships, conferences, and information of general interest. Much attention in the List is given to Morphology, Evolution, Developmental Biology, Speciation, and Palaeontology as these are the areas of interest of the List Owner and his Collegues from the Morphology Team of the Department of Vertebrate Zoology. All interested persons are invited to participate in the list as a subscriber and active participant. To subscribe either visit the homepage of the List at http://morphology.listbot.com or send a blank message to morphology-subscribe@listbot.com. For additional information, please contact the List owner: Yegor B. Malashichev (email: Yegor@EM1915.spb.edu).

Kansas Herpetological Society Annual Meeting

The KHS held its 26th annual meeting on 6 November 1999 at Pratt Community College in Pratt, Kansas, and included attendees from Kansas, Oklahoma, and Nebraska. Gregory Sievert (Emporia State University) received the "Suzanne L. & Joseph T. Collins Award for Excellence in Kansas Herpetology." The prize is awarded for photography in odd-numbered years, and for published contributions in even-numbered years. John Tollefson, an Emporia State University graduate student, was the recipient of the KHS Howard K. Gloyd/Edward H. Taylor Scholarship for a project on the Common Musk Turtle in Kansas. The scholarship honors the memory of two great biologists with strong ties to Kansas. Dwight R. Platt, Emeritus Professor at Bethel College, and graduate student Nicole Gerlanc, Kansas State University, Manhattan, were recognized as the first recipients of "The Big Croaker Awards," sponsored by the Kansas Department of Wildlife and Parks and the Kansas Amphibian Monitoring Program, and given to those individuals involved in the monitoring of amphibian populations during the spring of 1999. Each spring, over 100 KAMP volunteers census choruses of amphibians on eighty 15-mile routes across Kansas, establishing baseline information that will eventually be used to determine whether amphibian populations are declining, increasing, or remaining stable.

Southwestern Research Station Positions And Grants For 2000

VOLUNTEERS—Approximately 30 volunteer positions are open in 2000 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 14 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. Application due date: February 15, 2000. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reservations, answering phones, greeting guests, supervising volunteers, etc. Begin mid-March 2000 through September 2000. Five-day week; salary $235/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

Wildlife Links: Request for Proposals

The National Fish and Wildlife Foundation, through a cooperative agreement with the United States Golf Association, requests pre-proposals for projects that address wildlife conservation needs on golf courses. Areas of interest include: analysis of management and design techniques for increasing biodiversity on golf courses; research to determine if certain habitat characteristics result in wildlife corridors or barriers on golf courses; preparation of management guidelines for specific species or species suites; programs to monitor the success of wildlife habitat conservation programs on golf courses; and the effects of golfer and maintenance activities on wildlife. All projects must address issues of direct management concern to the golf industry, and should provide management recommendations applicable on at least a regional basis. Applicants selected to submit full proposals will be required to list contact information for partnering golf courses. Request should not exceed $30,000 per year, yet multi-year funding is possible. Deadline for preproposals is Friday, July 21, 2000. Applicants will be notified in August if a full proposal is requested. Full proposals will be due in October 2000, with funding available in February of 2001. For Wildlife Links preproposal guidelines, please visit the Wildlife Links program page on the National Fish and Wildlife Foundation's website, www.nfwf.org/nfwfusga.htm.

Rossman Retires from LSU

Douglas A. Rossman, Curator Emeritus at the Louisiana State University Museum of Natural Science, Baton Rouge, has retired from that institution and moved to Decorah, Iowa, where he has been appointed Research Associate in Biology at Luther College.

He continues to actively pursue research in snake systematics (especially on *Thamnophis* and *Helicops*), and he would welcome an ongoing exchange of ideas and reprints with colleagues. Correspondents may contact him at the Department of Biology, Luther College, Decorah, Iowa 52101, USA; tel. (319) 387-0988.

MEETINGS

International Roundtable on Chelonians: Heritage Collection Development, Restocking, and Relocation: 18–20 April 2000

Organized by the Ashton Biodiversity Research & Preservation Institute and the Desert Tortoise Council, and sponsored by the Chelonian Research Foundation, this three-day International Roundtable on Chelonians will be held immediately prior to the Desert Tortoise Council's Silver Anniversary Meeting in Las Vegas, Nevada (USA). The Roundtable Meeting will consist of presentations made by both Roundtable Members and by selected speakers. The goal of the International Chelonian Roundtable is to produce a very practical Protocol from which relocation and heritage collection programs can be planned, carried out, and evaluated using current knowledge. The Protocol will include both tortoises and turtles (excluding sea turtles). The target audience for the Protocol includes government conservation officials, conservation organizations, protected and natural areas managers and planners, animal welfare organizations, project managers, environmental consultants, private and public collection managers, and local community leaders. Registration and hotel reservation information may be obtained by contacting the conference organizers: Ghislaine Guyot or Ray Ashton, Ashton Biodiversity Research & Preservation Institute, Inc., 5745 SW 75th Street #331, Gainesville, Florida 32608, USA; fax 352-495-7433; tel. 352-495-7449; e-mail: GhGuyot@aol.com or Tortfarm2@aol.com.

Meetings Calendar

1–2 April 2000—All Florida Herpetology Conference, Florida Museum of Natural History, Gainesville, Florida. For more information contact Max Nickerson, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA (e-mail: maxn@flmnh.ufl.edu).

18–20 April 2000—International Roundtable on Chelonians: Heritage Collection Development, Restocking and Relocation. Las Vegas, Nevada, USA. *(Refer to meeting announcement above for details).*

15–20 May 2000—Workshop of Herpetologists, Tbilisi, Georgia. Contact: Prof. Zurab Tskvitinidze, Chairman, Society of Ecological Security, 150, Ave. David Agmashenebeli 380012, Tbilisi, Georgia; e-mail: ses@ip.osgf.ge or nhdc@ip.osgf.ge. Tel: (995032) 95-01-20, 96-78-38, 34-20-80, 38-74-56.

14–20 June 2000—43rd Annual Meeting, Society for the Study of Amphibians and Reptiles, together with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists, Universidad Autónoma de Baja California Sur, La Paz, BCS, México. *(Refer to meeting announcement on page 1 of this issue).*

11–15 July 2000—Sixth Biennial Joint Meeting of Portuguese and Spanish Herpetologists and the Tenth Biennial Congress of the Spanish Herpetological Association, Valencia, Spain. For more information contact: VI Congreso Luso-Espanol, X Congreso Espanol de Herpetologia, Departamento de Biologia Animal, Facultad de Ciencias Biologicas, Universidad de Valencia, 46100 - Burjasot, Valencia (Spain); e-mail: herp2000@uv.es. Web site: http://bioweb.uv.es/zoologia/AHE.

16–20 July 2000—Fourth Asiatic Herpetological Conference, Chengdu Institute of Biology, Chinese Academy of Sciences, Chengdu, China. For more information contact: Dr. Theodore J. Papenfuss, Museum of Vertebrate Zoology, Berkeley, California 94720-3160, USA; tel. (510) 642-3567; fax: (510) 643-8238; e-mail: asiaherp@uclink4.berkeley.edu.

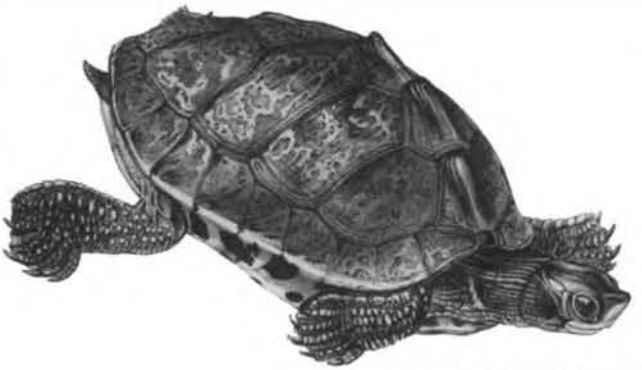
LEGISLATION & CONSERVATION

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles and their habitats. Please direct all communications to the section editor, **Travis Ryan** (postal and e-mail addresses on inside front cover).

USA: U.S. Fish and Wildlife Service—Office of Scientific Authority: On 12 November 1999 the Office of Scientific Authority—United States Fish and Wildlife Service submitted a proposal requesting that the spotted turtle (*Clemmys guttata,* Schneider 1792) be included in Appendix II of C.I.T.E.S. Briefly, the differences in Appendix I vs. II are the following: taxa listed in Appendix I are those species threatened with extinction, and are at present, or in the future, adversely affected by international trade. In general, Appendix I species are prohibited from entering international trade for commercial purposes. Conversely, Appendix II species may be traded internationally for commercial purposes, if all specimens are legally acquired and proper documentation is provided. Species categorized as Appendix II include those that may become threatened in the near future if international trade is not brought under strict control; therefore, such trade can not be detrimental to the species in question (USFWS 1998, *What you need to know about CITES permits & certificates. Fact Sheet Series, Office of Management Authority*). Trade in wildlife is a lucrative business that exploits numerous species both as living specimens and products. The importance of C.I.T.E.S. is clear. It is a conservation tool that assists with the controlled regulation of trade in endangered species and without it many species would perish. Therefore, the proposal concerning *Clemmys guttata* was drafted to circumvent a future Appendix I listing. This proposal will be evaluated and voted upon at the 11th meeting of the Conference of the Parties (COP11) in Nairobi, Kenya on 10–20 April 2000. A final statement expressing the outcome of the vote will be presented after adjournment of the convention. This proposed action was initiated by several factors, and these are mentioned below.

Spotted turtle habitats have been increasingly encroached upon

by urbanization and agricultural activities, and few areas remain unaltered. Specifically, habitat alteration and fragmentation can be caused by the introduction of invasive exotic plant species, grazing of livestock, draining and filling of wetlands, damming, ecological succession, and pollution. These events, if not curtailed, will only continue to add to the demise of this species (Behler 1996, Spying on Spotties. Wildlife Conservation 99[5]:38–45; Ernst et al. 1994, Turtles of the United States and Canada, Smithsonian Institution Press).



The Nature Conservancy (Heritage Distribution Ranking System) classified the spotted turtle as critically imperiled, imperiled, or vulnerable in 64% of its range (Data adapted from the Natural Heritage Central Databases, 1999). This, when compounded with low population densities, slow growth, delayed maturity, and high mortality of eggs and juveniles, makes *Clemmys guttata* especially vulnerable to population declines (Wilson et al. 1999, [Abstract] Symposium on the Conservation and Ecology of Turtles of the Mid-Atlantic Region).

Commercial trade at both the national and international levels is a problem. In a five-year period the United States has legally exported over 1200 adult specimens to overseas markets (*Note: 1999 data are incomplete; Data from USFWS-Division of Law Enforcement*). However, this estimate may be considered low due to undocumented or illegal activities. The domestic pet trade numbers are difficult to quantify; however, it has been suggested that a commercial collector in North Carolina legally took over 1100 spotted turtles over a two-year period (1993–94) (USFWS 1999, Proposal 11.37-Inclusion of *Clemmys guttata* in Appendix II). Over-collecting has been a concern in many states. Herpetologists and conservationists in Ohio and Indiana have expressed their concerns since the 1970s and 1980s, respectively. Legal, as well as illegal trade continues to impact spotted turtle populations, and such trade has been suggested to be responsible for population declines in 50% of the species' range (Litzgus 1996, Life-history and demography of a northern population of spotted turtles, *Clemmys guttata*. M.S. Thesis, University of Guelph).

Clemmys guttata qualifies for an Appendix II listing under the terms of the Resolutions of the Conference of the Parties 9.24, which states that, "Article II, paragraph 2(a), provides for the inclusion of species which may become threatened with extinction in Appendix II, in order to avoid utilization incompatible with their survival" (http://www.cites.org). This is explained in a brief summary below. Because the spotted turtle faces several threats, including international trade, it can be inferred that unless trade is regulated, it will meet minimally one of the biological criteria for an Appendix I listing. In addition, harvesting from the wild has a detrimental impact on the species by exceeding the level that it can be sustained indefinitely, thus further reducing population levels, to a point where the species can not rebound.

Additional information about this and other proposed listings can be obtained by visiting the C.I.T.E.S. website at http://www.cites.org/CITES/eng/index/shtml.

JUST REISSUED

SOWERBY & LEAR'S

TORTOISES, TERRAPINS, and TURTLES

This book is generally regarded as **THE FINEST ATLAS OF TURTLE ILLUSTRATIONS EVER PRODUCED**, drawn by the famous 19th century artists James de Carle Sowerby and Edward Lear. The short text is by John Edward Gray. Originally published in London in 1872, the book was reprinted by the Society for the Study of Amphibians and Reptiles in 1970 and again in 1984 but these copies were sold out some years ago. The reprint includes an extensive introduction by the late Ernest E. Williams, of Harvard University, detailing the history of the book and its authors and artists, and equating the scientific names to current nomenclature.

The atlas includes 61 black-and-white plates of turtles, depicting species from all parts of the world. The book measures 8½ by 11 inches (about 22 by 28 cm) and is clothbound. Copies can be purchased for US$40 ($35 to SSAR members, if ordered before June 2000) from the SSAR Publications Secretary, Robert D. Aldridge, Department of Biology, Saint Louis University, 3507 Laclede, St. Louis, Missouri 63103–2010, USA. Postage is extra (in USA, add $3.00; non-USA, add $5.00). Payments can be made on USA banks, by International Money Order, or may be charged to MasterCard or VISA (include account number and expiration date of credit card). Books can also be ordered by e-mail at ssar@slu.edu.

SSAR also publishes *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Herpetological Circulars, Catalogue of American Amphibians and Reptiles, Contributions to Herpetology,* and *Herpetological Conservation*. Inquiries about membership in the Society can be addressed to Dr. Aldridge (address above). A complete list of SSAR publications can be consulted at http://www.ukans.edu/~ssar/. Prices are effective through December 2001.

Testudo marginata. Illustration by P. A. Benson.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Jennifer Garrison** or **Christopher Sheil**; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.herplit.com/contents

Emergence Time of *Lacerta monticola* from Refugia

Martín and López studied variation in the emergence time of *Lacerta monticola* from refugia in the field, under different levels of predation risk. The authors present a special case of the Ydenberg and Dill model that describes the trade-off between risks and costs for prey fleeing to a refuge. Their model predicts that emergence time of *L. monticola* (or other ectotherms) from a refuge should vary as a function of risk of predation and thermal costs of refuge time. Field experiments support the conclusion that optimization of refuge utilization strategies might help lizards to deal with changes in predation risk without incurring excessive physiological costs.

Female Preference for Temporal Order of Call Components in *Physalaemus pustulosus*

The authors employed a Bayesian statistical approach to study female preferences for temporal relationships of the two parts of advertisement calls of conspecifics in *Physalaemus pustulosus*. Advertisement calls in this Neotropical frog are comprised of a whine (necessary for species recognition) and one or more chucks (which make the whine more attractive to females). Tests were conducted to compare the attractiveness of a whine with a chuck in a variety of positions relative to the start of the whine, against a normal whine or against a normal whine/chuck. Results of their experiments suggest that female *P. pustulosus* do have preferences for the temporal relationship of the two parts of the male advertisement call and that this preference exceeds the vocal signals produced by males. They also suggest that male calls have evolved to exploit one peak of this function.

Phenotypic Plasticity in Metamorphosing *Rana temporaria*

Phenotypic plasticity is a common phenomenon in nature that has been documented in many taxa. The authors examined tadpoles of *Rana temporaria* to determine whether or not they would exhibit phenotypic plasticity in metamorphic traits. Developing larvae were studied in laboratory experiments and were found to metamorphose sooner, and at smaller sizes, in response to decreasing water volume. Tadpoles were also less active in decreased water levels. It was determined that there was a positive correlation between activity late in the experiment and size at metamorphosis. Tadpoles also were found to develop more slowly in the presence of predators (dragonfly larvae). The authors conclude from their results that *R. temporaria* larvae do respond to pond-drying adaptively by increasing developmental rates, that temperature advantage is not needed to induce this adaptive plasticity, and that pond-drying is a more important determinant of developmental rate than is the presence of dragonfly predators.

Phylogeography of *Emys orbicularis*, the European Pond Turtle

Mitochondrial nucleotide sequences of the cytochrome *b* gene were analyzed by DNA sequencing and RNA heteroduplex analysis to infer the phylogeny and phylogeography of *Emys orbicularis*. This analysis of 423 individuals revealed incredible intraspecific differentiation in 20 haplotypes with distinct geographic ranges. Seven main lineages were identified within this species, and the authors suggest that this may reflect separations during the late Pliocene. Haplotype distribution revealed a substantial effect of glacial periods. The authors also suggest that this historical perspective indicates the existence of multiple glacial refugia, as well as considerable Holocene range expansion that was modulated by climatic traits.

LENK, P., U. FRITZ, U. JOGER, AND M. WINKS. 1999. Mitochondrial phylogeography of the European pond turtle, *Emys orbicularis* (Linnaeus 1758). Molecular Ecology 8:1911–1922.

Phylogeography of *Lampropeltis zonata*, the California Mountain Kingsnake

Rodríguez-Robles et al. studied the phylogeography of *Lampropeltis zonata* by examining mitochondrial DNA sequences from specimens belonging to seven recognized subspecies collected throughout the range of the species. Their analyses identified a basal split that corresponds to the southern (i.e., southern California and northern Baja California, Mexico) and northern segments of the species' distribution. Within the northern clade, the authors identified two subclades, a "coastal" subclade (populations from the central coast of California, as well as the southern Sierra Nevada Mountains of eastern California), and a northeastern subclade (populations north of the San Francisco Bay and the majority of the Sierra Nevada). These results suggest that the two deepest divergences within *L. zonata* may be the result of past seaways in southwestern California and the embayment of central California, both likely candidates as barriers to gene flow. The northern clade has apparently undergone instances of range contraction, isolation, differentiation, and then expansion followed by secondary contact. Recognition of seven geographical races in *L. zonata* may not be appropriate, owing to their lack of diagnosibility using conventional criteria of pattern and scalation differences as well as the lack of congruence with patterns of mtDNA differentiation.

RODRÍGUEZ-ROBLES, J.A., D.F. DENARDO, AND R.E. STAUB. 1999. Phylogeography of the California mountain kingsnake, *Lampropeltis zonata* (Colubridae). Molecular Ecology 8:1923–1934.

Ontogeny of the Bizarre

Trueb et al. describe the skeletal morphology and ontogeny of the direct-developing frog, *Pipa pipa*, based on observations of alcohol-preserved museum specimens. Osteologically, adult *P. pipa* may be distinguished from other pipids by its extremely depressed and hyperossified skull; however, the authors found the general sequence of chondrification and ossification to resemble that of another basal anuran, *Xenopus laevis*. Allometric transformations that result in the morphologically bizarre skulls of adults of this species were found to commence after metamorphic climax (marked by resorbtion of the tail), and ontogenetic comparisons reveal that the sacrum forms differently in *Discoglossus sardus, Silurana tropicalis,* and *P. pipa*.

TRUEB, L., A. PÜGENER, AND A. M. MAGLIA. 2000. Ontogeny of the bizarre: an osteological description of *Pipa pipa* (Anura: Pipidae), with an account of skeletal development in the species. Journal of Morphology 243:75–104.

The Influence of Habitat Structure on Migrating Juvenile Amphibians

The authors investigate the effects that different levels of canopy closure have on the movements of juvenile amphibians dispersing into upland habitats. Natural populations of Wood Frogs (*Rana sylvatica*) and Spotted Salamanders (*Ambystoma maculatum*), as well as artificial populations of *R. sylvatica* were monitored for four months using mark/recapture and pitfall traps in both linear and circular arrangements. The natural populations were located adjacent to a recent forest clearcut, where experimental pools were placed bordering a power line right-of-way. In all cases, juveniles were found to emigrate preferentially to closed-canopy habitat. In natural populations, where adult density was also monitored, the adults of both species were more abundant in mature forest interior habitats than in either edge or clearcut habitats. Density of foliage in both the understory and canopy layers was found to be important to anuran density and diversity. Management implications include the importance of habitat connectivity between upland and breeding habitat for migratory populations of amphibians. The authors suggest further investigation be undertaken on a larger scale to determine the effects of canopy removal on genetic and demographic characteristics of similar populations.

Effects of Land Use on Anuran Abundance

Anuran call surveys and land use maps were used to examine landscape-level patterns of habitat use by frogs and toads in Iowa and Wisconsin. The authors measured landscape variables including land use (e.g., amount forested, presence of urban land and area of permanent and temporary wetlands), amount of edge, and fractal patch dimensions. Multiple regression and principal components analysis (PCA) were employed to determine the effects of individual landscape variables on anuran abundance and richness, and on guild associations, respectively. The strongest correlations were between urban land use and anuran guilds in both states (negative), and a positive correlation between forests (both upland and wetland) and emergent wetlands and anurans. The authors stress the importance of determining such landscape-level relationships between habitat and anuran abundance and species richness in efforts to reverse the widespread amphibian decline. They suggest that the definition of these areas will allow a prioritizing of sites for conservation and restoration.

The Influence of Historical Factors on the Community Ecology of Amazonian Lizards

Contrary to the often-held belief that present-day factors (e.g. competition, predation) drive patterns of community structure, the authors found historical factors exerted the greatest influence on the lizard assemblage in the Curuá-Una in the central Brazilian Amazon. The nineteen co-occurring species were found to separate on the basis of micro-habitat and prey type, but not on the basis of time (of activity). The dietary similarities were correlated with phylogenetic similarities, while microhabitat similarities were not. The authors regard these results as suggestive of an historical impetus for the current community structure. The lizards found at this site are from a variety of families, suggesting that historical factors may play a more important role in phylogenetically deeply rooted assemblages than in those that are more shallowly rooted.

Habitat niche breadth was found to be a poor predictor of dietary niche breadth. Ecological factors that allow for species to coexist may have been present before the species came into contact with one another. If true, this could reduce the importance of in situ species interactions. This study investigates several niche axes (time, space, food) quantitatively, in an evolutionary framework.

Drinking Mechanisms in Two Iguanid Species

The authors investigated the hypothesis that iguanid species found in areas with different patterns of water availability would utilize different drinking mechanisms. The study animals were the arboreal species *Anolis carolinensis*, found in the southern United States, and *Oplurus cuvieri*, of northwestern Madagascar. While water is constantly available to *A. carolinensis*, it is only seasonally plentiful for *O. cuvieri*. The kinematic analysis using x-ray and high-speed cinematography film revealed a similar drinking mechanism used by both species when water is rare. However, whereas *A. carolinensis* uses the observed pattern regardless of water availability, when water becomes more available, the role of the tongue in the process of water collection and swallowing is diminished in *O. cuvieri*. The authors suggest that this, and further studies, will allow for the modeling of the evolution of the lingual and hyoid elments.

Origin of Clouded Salamanders on Vancouver Island and a New Species of *Aneides*

Jackman uses genetic evidence (both allozymes and mitochondrial DNA) to establish that populations of *Aneides ferreus* (Clouded Salamander), which are widespread on Vancouver Island and nearby smaller islands, are nearly identical with those from an area in northwestern California. Jackman makes a case for introduction of salamanders to Vancouver Island via extensive shipments of Tan Oak bark during the nineteenth century. Historical records of shipments and the methods by which bark was gathered and stored prior to shipment lend support to Jackman's hypothesis. Additonally, the genetic evidence indicates that California and Vancouver Island populations are distinct from those in Oregon, and in an appendix, Wake and Jackman describe these as a new species, *Aneides vagrans*. The two species meet and narrowly overlap in extreme northwestern California, and there is evidence of some introgression, but no clear hybrid individuals have been identified.

JACKMAN, T. R. 1999 (1998). Molecular and historical evidence for the introduction of clouded salamanders (genus *Aneides*) to Vancouver Island, British Columbia, Canada, from California. Canadian Journal of Zoology 76:1570–1580.

The Use of Electronic Temperature Devices In Thermoregulation Investigations

A replicated experiment was used to test the ability of electronic temperature recording devices to generate measurement series similar to those produced using standard copper models of lizards. The authors tested both an external probe device (HOBO XT™) and a self-contained (Tidbit™) temperature recording device against models constructed of copper and painted with acrylic paint to represent *Sceloporous undulatus* and *Scincella lateralis*. The temperature probes were both found to produce results almost identical to those obtained from the more expensive and complex copper models. This suggests that the electronic devices might be effective as proxies for biophysical models in some investigations, and that size, morphology, scale architecture, and color contribute little to temperature change in the models of small vertebrates. Pilot studies of these devices should be performed in investigations of other animals, as the present study focuses exclusively on small-bodied lizards. The authors advise that the external probes provide excellent null temperature distributions, but do not respond as quickly to temperature change as copper models or Tidbits.

VITT, L. J., AND S. S. SARTORIUS. 1999. HOBOs, Tidbits and lizard models: the utility of electronic devices in field studies of ectotherm thermoregulation. Functional Ecology 13:670–674.

Ernest Edward Williams 1914–1998

CARL GANS
Department of Biology
The University of Texas, Austin, Texas 78712, USA
e-mail: carolus@uts.cc.utexas.edu

On 1 September 1998 died Ernest E. Williams, long the Curator of Herpetology at the Museum of Comparative Zoology at Harvard College. He was born in Easton, Pennsylvania on 7 January 1914 and his death marked the end of an era of spectacularly diverse herpetological researches at the Museum.

Photograph by M. Graham Netting, courtesy of Kraig Adler.

Ernest was a very private person; even those of his students who knew that he would visit relatives in Pennsylvania at the end of the year did not know details of the relationship nor had they met the relatives. In Cambridge, his residence proved to be in various sets of furnished rooms and he subsidized local restaurants all within walking distance of the Museum. The available kinds of mixed alcoholic beverages provided a key for the selection of restaurants. Visitors would be taken to lunch at whatever the current restaurant of choice; these were mostly located in the vicinity of Harvard Square. Graduate students were generally permitted to join these lunches, which were highly desirable events for them, as beyond the current visitors, lunch might include the company of A. S. Romer and Brian Patterson, and later of Ben Shreve. The conversations were generally wide-ranging and questions were encouraged. Beyond these lunches, Williams developed the pattern of arranging spectacular parties, designed in part to reciprocate the hospitality of colleagues. Often the execution was turned over to graduate students and their companions, but Ernest always provided an open purse and maintained quality control.

Ernest had spent much of W.W. II with the U.S. army in Europe. Whereas he rarely talked about this period, one was reminded thereof as he had obtained the stamp of the registrar's office of a German village and this became the "Ex libris" of the M.C.Z. herpetological library. After discharge from the army, he matriculated at Columbia under William King Gregory and after the latter's untimely death, became the student of G. G. Simpson. His dissertation topic was the neck skeleton of turtles, later published on in the American Museum *Bulletin* and these animals Recent and fossil provided Ernest with many research topics for the following decade.

In 1950, Ernest moved to Cambridge to become Assistant Professor with Alfred Romer, mainly assisting in teaching the famous Comparative Anatomy course. He also loosely supervised some of Romer's students, such as Thomas S. Parsons and Paulo E. Vanzolini. Furthermore, he collaborated with Arthur Loveridge who had long curated the Museum's herpetological collections. Their monograph of the African cryptodire turtles (published as a M.C.Z. *Bulletin*) proved a hallmark in African herpetology, although their viewpoints were hardly congruent [see footnote on the first page]. 1957 marked Loveridge's retirement from the curatorship and move to Saint Helena. Harvard appointed Karl P. Schmidt as head of the succession committee and Williams was appointed to take over the curatorship that fall. The occasion was marked by a new card gracing the entry to the main herpetology office and proclaiming that "persons bearing turtles will be received."

The implication of this announcement proved to be very much of an overstatement, as Ernest had personal interest in many other topics, involving a wide range of organisms and many, generally evolutionary, research topics. It seems useful to mention pattern variation of *Hyla crucifer*, and *Plethodon cinereus* as these and many other distinct evolutionary studies were never completed. With Tom Parsons he carried out reports on the dentitional patterns of the three major groups of amphibians. A bit later he revisited the embryologic and phylogenetic pattern of the vertebral column of amphibians and reptiles, an issue that had long been confused by reliance on Hans Gadow's notes, which had regrettably been published in a posthumous book. As critical as Ernest's eclectic research interests was Ernest's willingness to supervise and help with the research by many undergraduate and graduate students on a very wide range of topics. He was known to concentrate on the project being presented and to offer his full attention during oft-extended discussions, no matter how long it took. I shall never forget the two full days during which he dissected the "final" version of my dissertation and the resulting and to me astonishing improvement he generated.

Ernest liked to write and took great pride in polishing his products. His expository style was concise and subtle and has been referred to as inspirational. Whatever, he was unexcelled in his ability to summarize areas and crisply to state the issues involved. The resulting summaries were often less than kind whenever they addressed the failings of students, colleagues or administrators. Ernest's ability to handle the English language was clearly associated with his enormous capacity for the consumption of literature, both highbrow and profane.

Ernest gradually changed the pattern of collection acquisition for herpetology as he encouraged students to acquire major sets of specimens from diverse regions. He concurred that it was critical to collect and store series of specimens, rather than individual exemplars. Some such materials could be obtained as he had Mr. Benjamin Shreve member of a distinguished Boston family who served for decades as an unpaid volunteer herpetologist in the department. Shreve's willingness and ability to identify materials and to publish on individuals of new forms increased the capacity

of the MCZ to handle small collections. Whereas, Mr. Loveridge had been severely limited in the funds available to him and had consequently restricted the magnitude and number of exchanges, Ernest managed to overcome this limitation, in part by use of grant [and personal] funds. Repeatedly he hosted visitors [such as Ray Laurent from Zaire] for protracted periods and helped them with their research, also trying to obtain some portion of the collections involved for the MCZ. A special example of this help and exchange procedure involved the extensive collections of Fred Parker from Papua New Guinea and the Solomon Islands. Fred had failed to interest other curators, but Ernest accepted the collections and the responsibility of dealing with them. He arranged for the publication of large portions thereof, but [with Parker's permission] also transferred series to other museums. Many frogs went to the American Museum and snakes to the California Academy of Sciences.

The result of these activities was that the Museum's collections increased from 72,550 to 303,925 during his tenure. These numbers hardly characterize the importance of the collections, which included many types and representative examples of vast African holdings. These resources allowed Ernest to collaborate with the paleontologist Richard Estes and he allowed the students of Estes to prepare skeletal materials even of rare species. Estes' several later monographs of lizard systematics derive primarily from these materials. Some time in the nineteen seventies the collections achieved the benefit of a full-time collections manager, under an NSF grant and July 1977, marked the advent of Mr. José Rosado, who not only cared for the museum materials, but appreciated Ernest as a person and helped him extensively during his final years as his health became more fragile.

During the first years of his curatorship, Ernest became deeply interested in the fauna and biogeography of the Caribbean islands. This led to a concentration on iguanid lizards, particularly on the genus *Anolis*. As his studies expanded he published an "Anolis Newsletter," initially planned as progress reports to the National Science Foundation. Even a brief scan of these reports showed the vast range of Ernest's interests, zoogeography, ethology, morphology, whatever were grist for his mill. Many ecological and zoogeographical principles were thus exemplified. The historical account in the SSAR "Contributions to West Indian Herpetology" provides an excellent overview of the importance to the Caribbean studies, both in the work Ernest carried out himself and in his encouraging the efforts of many students and other colleagues. Issues of island zoogeography were expanded with the aid of collaborative studies with P. E. Vanzolini that stressed issues of continental zoogeography. Indeed he had discussed his plans for a volume of zoogeography, but this never came to fruition. Another topic that remained in draft stage was an enormously ambitious analysis of lizard scalation using scanning microscopy; some hundreds of notebooks filled with photographs still remain unpublished.

After the academic program at Harvard allowed it, he started to teach a single course entitled "Biology of Amphibians and Reptiles," which was basically herpetology from the perspective of evolutionary biology and taught the course from the point of view of contemporary problems. Not only did this allow the students to recognize current problems, but it kept the course fresh and interesting for himself. The rich resources of the department, both literature and specimens, underpinned the course.

Although he was not a joiner, or meeting goer, and the large number of students he supervised never came to be seen as a "school," a concept that amused him, he did receive numerous recognitions, such as a Guggenheim Fellowship. A volume in his honor (edited by A. Rhodin and K. Miyata) appeared upon his retirement in 1980, and the diversity of the 68 contributors and of their chapter topics documents the breadth of his interests [the incorporated biographical statement by P. E. Vanzolini contains an interesting and somewhat different viewpoint of his professional career.] Ernest remained as a half-time Professor until his official retirement in June 1984. Throughout his career he was a scholar with diverse interests. He had an outstanding influence on many herpetologists and other biologists, on students and colleagues, not only because of his scholarly publications, but also through his discerning and stimulating discussions. We all learned much from him.

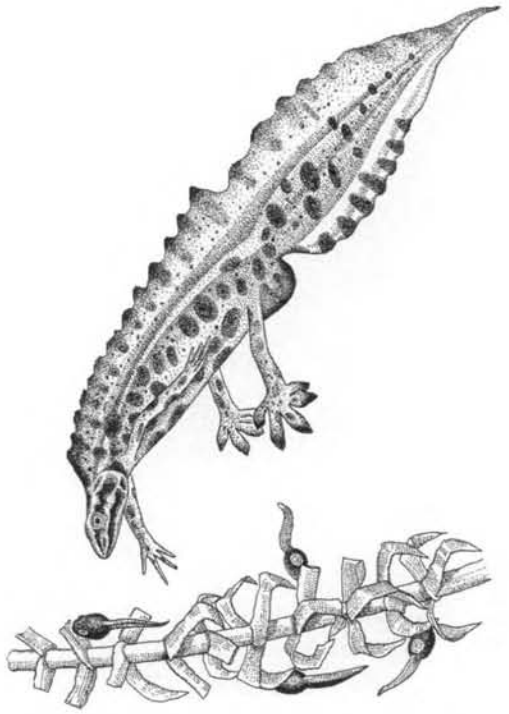
Annual Meetings



HENRY R. MUSHINSKY
Department of Biology, University of South Florida
Tampa, Florida 33620, USA
e-mail: mushinsk@chuma.cas.usf.edu

So, where will the next annual herpetology meeting be held? Did you go to the annual herp meetings at Pennsylvania State University this past summer? Are you planning to go to the meetings in La Paz, Mexico next June? What about the 2001 annual meeting scheduled for Indianapolis; will you go to that one? As many of you who read *Herpetological Review* already know, attending the annual meeting of herpetologists is always rewarding, informative, and just plain fun. For most, the annual meeting is a chance to renew oneself, an opportunity to recharge. Annual meetings provide a venue to see old friends, past graduate committee members, and former students. For students and other neophytes to the field of herpetology, an annual meeting provides an opportunity to meet, face to face, the authors of the papers and books they have read. Virtually without disagreement, those who attend and participate in the annual herpetology meetings leave the venue feeling refreshed, rejuvenated and ready to meet the next set of challenges. You have had the opportunity to publicize your research, get some informal feedback, and incorporate the ideas of your colleagues into your research. You also have had the opportunity to learn what others in the field are doing a year or two before you will have the chance to read about the research results in your favorite journal. The reasons for attending annual meetings of herpetologists are manifold and varied, but virtually all who go are glad they did.

Consider this essay your personal invitation to get more involved with your fellow herpetologists, by hosting an annual meeting at your institution. As Chair of the Meeting Site Selection Commit-

tee for both the Society for the Study of Amphibians and Reptiles and The Herpetologists' League, I invite you to get involved. While hosting an annual meeting is a large responsibility that requires considerable planning and forethought, the rewards for a well-executed meeting are equally large. You get an opportunity to showcase your university, to put your research laboratory on the national herpetological map, and to entice students to apply to work with you. Depending upon location and timing, a typical SSAR/HL meeting will attract between 400 and 600 individuals. Many relatively small universities can readily accommodate groups of this size during the summer months. I and others who have gained experience running annual herp meetings are very willing to help you organize your meeting and will provide any needed guidance.

One comment heard frequently at recent annual meetings has been that the high costs of the meeting are preventing graduate students from attending, a trend that likely will continue at the La Paz and Indianapolis meeting sites as well. Meeting in large hotels or conference centers causes the costs to be much higher than the more traditional meetings held on a college campus. You can help yourself and your professional societies by getting involved in our annual meetings. Please give this invitation your serious consideration. If interested, please contact me at the email provided above. I look forward to working with you to create the best meeting ever.

A New Herpetological Circular from the Society for the Study of Amphibians and Reptiles

LINEAGES AND HISTORIES OF ZOO HERPETOLOGISTS IN THE UNITED STATES

BY

WINSTON CARD AND JAMES B. MURPHY

HERPETOLOGICAL CIRCULAR 27

This new publication provides a complete lineage of over 200 zoo herpetologists and keepers for 57 US zoos. An historical section provides short vignettes of all retired zoo herp curators dating back to Arthur Brown in 1876, and includes 54 photos, most of which have never been published. Card and Murphy offer new insights into the world of zoo herpetology. iii + 44 pages. ISBN 0-916984-51-6. February 2000.

Prices: Prepublication (*SSAR members only*): US $7.00 postpaid. Additional copies $4.00 postpaid.
After 31 July 2000: US $8.00 + $2.00 shipping (add $1.00 shipping for each additional copy placed with same order).

Send orders to: Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, 3507 Laclede Ave., St. Louis, Missouri 63103-2010, USA; e-mail: ssar@slu.edu. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MasterCard (include account number and expiration date of credit card). SSAR membership details and a complete list of Society publications can be consulted at http://www.ukans.edu/~ssar/.

How Many Reptile Species?

PETER UETZ
Department of Genetics, University of Washington
Box 357360, Seattle, Washington 98195, USA
e-mail: uetz@u.washington.edu

Vertebrates are certainly the best-studied animals of which most species have been identified. Accordingly there are comprehensive compilations that list all known 4675 mammal species (Hutterer 1995; Wilson and Reeder 1993), all 9702 birds (Sibley and Monroe 1993), 4780 amphibians (Duellman 1993; Frost 1985; Glaw and Köhler 1998) and 23,250 fish (Eschmeyer et al. 1998). Nevertheless, new fish, amphibians, and reptiles continue to be described at a rate of about 200, 80, and 60 species per year, respectively (Bauer 1999; Eschmeyer et al. 1998; Glaw and Köhler 1998; this work). Two comprehensive lists of reptile species have been attempted recently (Ananjeva et al. 1988; Frank and Ramus 1995) which list 7712 and ~6700 reptile species, respectively. However, both have shortcomings: they are mere lists of names that do not distinguish between original and secondary names (Frank and Ramus 1995) or do not give the year of description (Ananjeva et al. 1988); they do not list synonyms, statistics, or distributional data; and they provide no references to individual species. Finally, as with most printed lists, corrected updates are not forthcoming and likely would soon be out of date again. Interestingly, misconceptions about the diversity of reptiles persist. For example, two randomly selected textbooks on biodiversity (Becher 1998:92; Margulis and Schwartz 1998:331) mention the existence of 6300 and 5000 reptile species, respectively. The latter number neglects 37% of all described species!

To overcome such shortcomings we started an online database of reptile species about four years ago (Uetz and Etzold 1996). This list currently contains 7870 extant reptile species and provides not only synonymies and distributional data, but also attempts to give references for every species. The database has been assembled mainly from published monographs and checklists and from submissions by individual contributors. Currently, it contains original references for about 75% of the known reptile species and provides links to photographs of more than 1000 species on the World Wide Web. Eventually the database should serve as a guide to descriptions and keys in the literature or even contain them as online information. Together with the recently established amphibian species checklist (http://www.mabnetamericas.org/; see also http://research.amnh.org/herpetology/amphibia/index.html), this database completes the lists of more than 50,000 vertebrate species names that are available online.

The majority of reptile species are the lizards (4470 species) and snakes (2920), whereas the turtles (295), crocodiles (23), and tuataras (2) represent only 4.1% of all living reptiles. 51% of known reptile species belong to one of only three families: the colubrid snakes (about 1850 species), the skinks (1200), and the geckoes (1000). Fig. 1 summarizes the assignment of extant reptile species to their families. Furthermore, I assembled a preliminary world reptile diversity map that illustrates species richness in different geographic areas of the world (Fig. 2). The database is easily queried for individual countries or subordinate areas, although incomplete data yield more erroneous results for national and subnational regions like states or provinces.

I am aware that such a database will never be complete, simply because new species are constantly being discovered and because new phylogenetic insights lead to taxonomic and nomenclatural rearrangements. Furthermore, species concepts in herpetology changed, especially with the influential paper of Frost and Hillis (1990), who proposed adoption of an evolutionary species concept (ESC) as opposed to the hitherto used biological species concept (BSC). The ESC suggests the recognition of "diagnosable" evolutionary units or populations as species. This suggestion led to the elevation of many subspecies to species status. Unfortunately, the ESC has been applied very unevenly and often without proper study and therefore many taxonomic and nomenclatural changes will follow. In fact, this is also true for other vertebrates such as birds (Haffer 1997). The increasing popularity of molecular studies is another factor that will cause significant rearrangements and nomenclatural changes within many taxa, simply because morphological analysis often does not resolve the phylogenetic relationships between both distantly and closely related taxa or even gives contradictory results (see for instance Hedges and Poling 1999). Retrieval of DNA sequence data from the reptile species database is facilitated by its location on the European Molecular Biology Laboratory server which not only hosts GenBank and related databases but also uses the same query interface.

The EMBL Reptile Database (http://www.embl-heidelberg.de/~uetz/LivingReptiles.html) is a starting point for further developments. Its shortcomings can be overcome by regular review by specialists. Collaborations with several herpetological societies are currently being negotiated. Until decisions are reached, I solicit all systematic herpetologists to communicate taxonomic changes as well as errors or omissions.

Acknowledgments.—The database described here could not have been realized without the help of many individuals, too many to list here but who are listed on the database's website. I thank Gerard Cagney, Bill Duellman, Jakob Hallermann, Ray B. Huey, Mirco Sole Kienle, and George Zug for helpful comments on earlier versions of this manuscript.

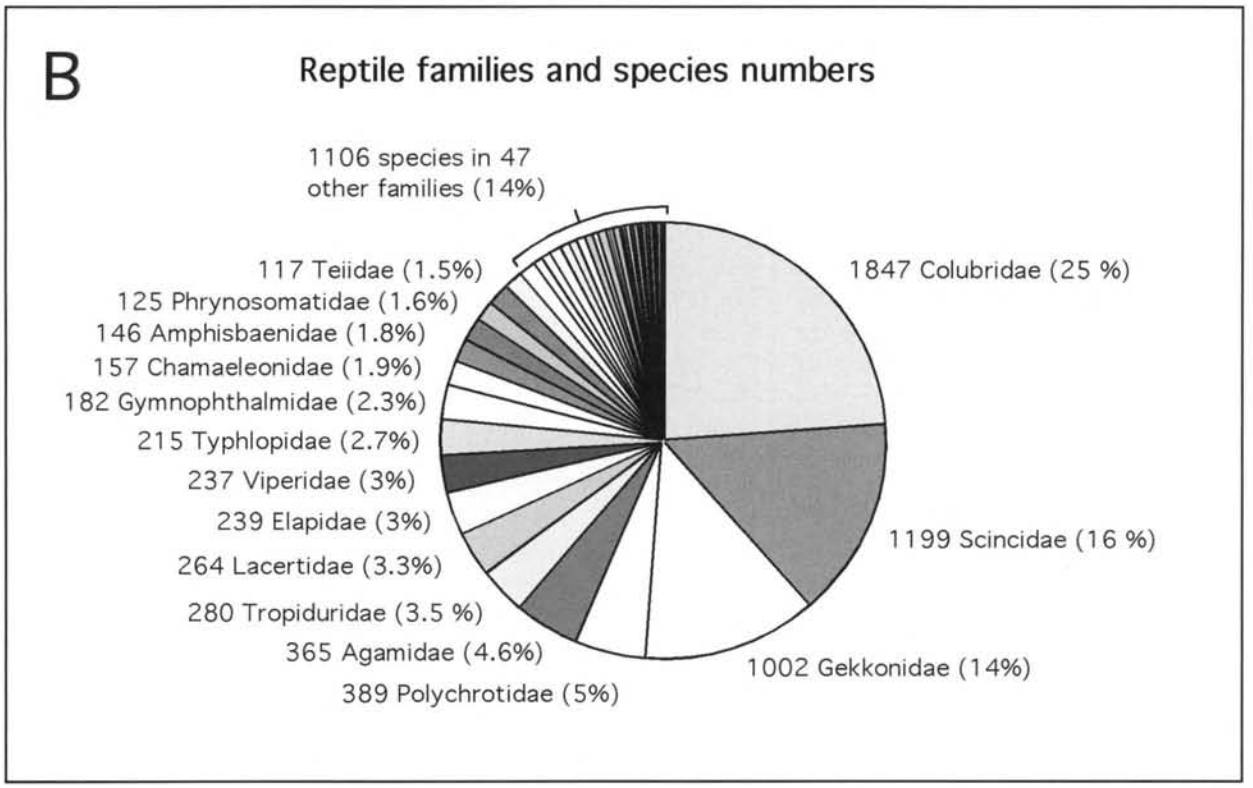

FIG. 1. Absolute species numbers and their percentage of the major extant reptile families. A. Higher taxa. B. Individual families. This chart uses a rather traditional classification with the Gekkonidae containing the Eublepharidae but not the Pygopodidae. The iguanian families have been split according to Frost and Etheridge (1989). Some authors have suggested reverting to the traditional family "Iguanidae" (e.g., Macey et al. 1997), which would form the fourth-largest family with 865 species. Elapidae and Hydrophiidae are treated as separate families. Numbers for the smaller families can be retrieved from our web site. The numbers are available at our web site and will be updated regularly.

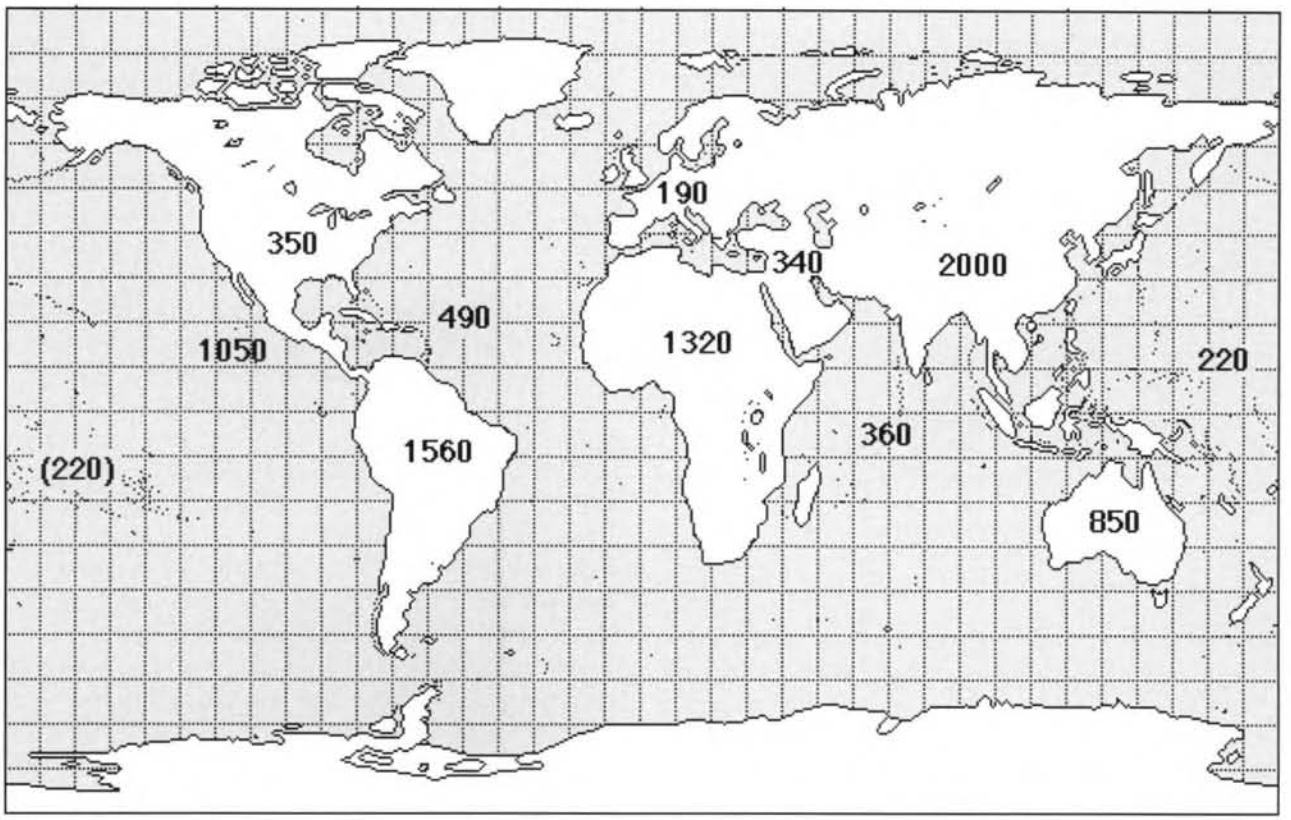

FIG. 2. Species numbers for different continents or geographic areas: Africa (1320), Asia incl. New Guinea (2000), Australia (850), Caribbean (490), Europe incl. Canary Islands (190), Indian Ocean incl. Madagascar, Comoros, etc. (360), Middle America (1050), Near East incl. Iran, Iraq (340), North America (350), Oceania incl. New Zealand (220), South America (1560). The sum of these numbers (8750) exceeds the total number of species (7870) because some species occur in several of these areas (e.g., 125 species occur both in Panama and Colombia, i.e., Middle and South America). Numbers in the figure have been rounded to the nearest 10. Numbers for individual countries can be found online in the EMBL Reptile Database. This map is available at the web site and will be updated with future releases of the database.

A substantial degree of broad and local scale geographic variation in life history traits (e.g., body size, age and size at maturity, egg size, clutch size and frequency) has been documented in the painted turtle (*Chrysemys picta*)(Iverson and Smith 1993; Lindeman 1996; Rowe 1994, 1997). Painted turtles are generally omnivorous (Ernst et al. 1994) and high degrees of carnivory may be positively related to growth rates, body size, and reproductive output among populations of painted turtles (Gibbons 1967; Gibbons and Tinkle 1969; Lindeman 1996; MacCulloch and Secoy 1983). Recently, Lindeman (1996) summarized the literature on painted turtle dietary habits and found extreme carnivorous or herbivorous populations throughout the range of the species. In order to attribute some of the variation in life history traits to variation in dietary habits of painted turtles, we clearly need more data on the diets of painted turtles throughout their distribution (Lindeman 1996).

We studied the dietary habits of adult midland painted turtles *(Chrysemys picta marginata)* at Miller's Marsh on Beaver Island (W85°30.89'; N45°38.06') located in northern Lake Michigan, USA. Miller's Marsh was a small marsh system (max depth approx. 1.5 m and about 4–5 ha in surface area) with dominant submergent vegetation that included *Nuphar variegatum*, *Potamogeton amplifolius*, and *P. natans*. We collected painted turtles in baited fyke nets between 30 June and 5 July, 1994 and between 5 June and 2 August, 1995. Upon capture, carapace length was measured to the nearest 1 mm using calipers, body mass was measured to the nearest 10 g using a spring scale, and stomach contents were obtained by stomach flushing (Legler 1977). A weed spray can was used to deliver water through a rubber tube (0.5 cm diameter) that was inserted through the mouth and into the stomach. Turtles were held by hand and a rubber stopper was used to keep the turtle's mouth open during flushing. Stomach contents were collected in a screen strainer and placed in 10% formalin until processing. We conducted flushing on each turtle until we were reasonably sure that no more food would be obtained. To evaluate the efficacy of our flushing technique, we dissected three males after obtaining positive flushes and found that one individual had a minute quantity of filamentous algae adhered to the mucosa of the stomach. We otherwise found no measurable quantity of food in the stomachs which indicates that our flushing technique was probably a reliable way of obtaining food samples. Samples were later sorted, taxa identified, separated into animal and plant matter, and then dried in an oven for 24 h at 75°C. To determine the amount of organic material present in the diet, the dried samples were weighed to the nearest 1 mg and burned in a furnace at 550°C for 1.5 h to determine ash free dry mass (Steinman and Lamberti 1996) measured to the nearest 1 mg.

We obtained prey items from 35 (11 in 1994; 24 in 1995) of 48 turtles flushed. Mean (± 1 SD) carapace length and body mass were 151.1 ± 7.46 mm (112–162 mm) and 417.3 ± 77.41 g (190–580 g) respectively for females (N = 21) and 139.6 ± 5.07 mm (132–145 mm) and 320.7 ± 53.68 g (220–340 g) respectively for males (N = 14). Frequencies of ingested prey items are presented in Table 1. The most frequently ingested animal prey were damselfly larvae (Zygoptera) and caddisfly larvae (Tricoptera), each present in about one third of all stomach samples. Other aquatic insect larvae or pupae were of lesser importance and included dipterans, especially midge larvae (Chironomidae; up to 168 individuals per stomach), dragonflies (Anisoptera), and beetles (Dytiscidae). A few adult insects were also eaten, particularly back swimmers (Notonectidae) and bees (Hymenoptera). Crustaceans were not a substantial dietary component although a few stomachs contained cladocerans (>1000 per stomach in one individual turtle) and an occasional scud (Amphipoda). Vertebrates were not frequently ingested although we did find some aquatic salamanders (two *Ambystoma laterale* larvae and one adult *Notophthalmus viridescens*) and an anuran tadpole. The most frequently ingested plant material was unidentified plant material and detritus although *Nuphar variegatum* seeds (up to 140 per stomach) and pulp were found in about 50% of all stomach samples. Filamentous algae was represented in only about 11% of all stomach samples.

The painted turtles of our population were omnivorous. On a frequency of occurrence basis, plants and animals were ingested with about equal frequency (plants: 83.3% of all stomachs vs. animals: 77.8 % of all stomachs; $\chi^2_{df=1} = 2.1$, $P > 0.05$). Both animal and plant matter were found in 21 of 35 stomachs although some stomachs contained only animal matter (N = 6) or only plant matter (N = 8). On an ash free dry mass basis, the percent of animal versus plant material expressed as the total quantity of food ingested was 18.2% and 81.8% respectively. However, this disparity probably reflects the effects of a few stomachs that contained substantial quantities of *Nuphar variegatum* and it should be noted that the seeds of *Nuphar variegatum* are apparently not digested as evidenced by their presence in turtle feces. The average percent of plant ash free dry mass in individual stomachs was 52.4% (SD = ± 0.44%, N = 35) while animal material represented the other 47.6% (SD = ± 0.44 %, N = 35). There was no significant difference in the amount of animal versus plant ash free dry mass consumed by individuals (Wilcoxon signed-rank matched pairs test, $P = 0.46$).

A number of animal and plant prey items have been reported for *C. picta* (see Ernst et al. 1994 and Lindeman 1996) and our sample seems fairly typical for the species. Our painted turtles were probably active predators that obtained much of their food by foraging along the soft benthos or aquatic vegetation for aquatic insect larvae and occasionally catching adult arthropods or amphibians as was observed by Sexton (1959). Cladocerans have been reported

TABLE 1. Frequency of occurrence of prey items expressed as a percentage of the total number of stomachs (N = 35) that contained a particular prey item in *Chrysemys picta*. Adult = a, larva = l, pupa = p, and UID = unidentified.

Taxon	Frequency of Occurrence (%)
ANIMAL MATERIAL	77.8
Insects	
Odonata	52.8
Anisoptera	19.4
Zygoptera	33.4

Nuphar	50.0
Algae	11.1

previously in the diets of painted turtles (Brown 1992; MacCulloch and Secoy 1983). Juvenile *C. picta* apparently ingest cladocerans individually (Brown 1992) although because our turtles were relatively large adults, we doubt whether the large numbers of minute cladocerans were ingested individually. More likely, turtles located aggregates of cladocerans and ingested several simultaneously by forming a vacuum with the pharynx. While adult aerial insects, such as flies and bees, may have been scavenged after they fell into the water, it is possible that some prey were eaten by extending the head from the water and capturing stationary prey located on overhanging vegetation as we have observed on three separate occasions.

It is often difficult to determine whether plant matter is ingested incidentally with animal prey or is the primary food item (Lindeman 1996). The relatively large quantity of *Nuphar variegatum* present in our samples however, indicates that this plant matter was intentionally ingested. Turtles apparently ate the flower heads when the aging stems bent and allowed the formerly upright flower heads to become submerged. However, some unidentified decomposed vegetation and small quantities of small unidentified fresh plant particles may have been incidentally ingested during the consumption of animal prey.

A number of factors are likely to influence variation in the dietary composition within and among painted turtle populations. Lindeman (1996) detected seasonal effects in Idaho and Washington western painted turtle populations. In our population, such seasonal effects probably occurred as aquatic insect pupae metamorphosed early in summer and *Nuphar variegatum* flower heads became available and then deteriorated later in the summer. While we did not statistically account for seasonal effects, our samples were obtained throughout the summer months and so our data should be representative of the dietary habits of the adults of our population during that time period. Because it is difficult to stomach flush small individuals, we were unable to address whether juveniles were more carnivorous than adults as has been observed in other populations (Gibbons 1967) but not others (Lindeman 1996).

Acknowledgments.—We thank J. C. Gillingham and Central Michigan University Biological Station for laboratory space and logistic support during the study. We also thank R. Ballinger, G. Smith, R. King, D. Wujek, and B. Young for their assistance during preparation of the manuscript. The study was funded partially by the Faculty Research Funds at Daemen College.

Cayo Pisaje is a small key (0.29 km^2) located 0.35 km off Punta Regalada near the town of Juancho on the eastern coast of the Barahona Peninsula, Dominican Republic (Fig. 1). The island, with a maximum elevation of <3 m, supports five different habitats: 1) sandy beach littered with flotsam; 2) high tide limits, representing an area of integradation between short scrub and beaches and dominated by sea purslane *(Sesuvium portulacastrum)*; 3) short scrub; 4) arborescent areas composed of mangrove trees *(Rhizophora mangla)* and sea grapes (*Coccoloba uvifera*); and 5) a grassy depression, centrally located and retaining water at least during the rainy season. The mean temperature of Enriquillo, a coastal town, situated ca. 9 km to the north, is 26.9°C, and the mean annual rainfall is 1349.2 mm (Salcedo et al. 1983). Precipitation in the area follows a bimodal pattern, one wet season occurring in the late spring, the other in late summer/early fall. The island is uninhabited although unoccupied campsites, used occasionally by fishermen, are present.

Schwartz and Henderson (1991) listed three lizard species from this island: *Leiocephalus barahonensis barahonensis, Aristelliger expectatus,* and *Sphaerodactylus randi strahmi*. This number seemed low in light of the island's proximity to the main island and in comparison to the number of species in adjacent areas on the main island. We spent 22 person hours on Cayo Pisaje on 14 June 1999 in order to survey the herpetofauna. Only a few voucher specimens of each species encountered were collected in order to minimize any impact on island populations; all were deposited in the Bobby Witcher Memorial Collection (BWMC) at Avila College.

We found three species of lizards, representing three families. *Anolis brevirostris wetmorei* had not been recorded previously. We failed to find one species, *Sphaerodactylus randi strahmi,* listed by Schwartz and Henderson (1991).

Leiocephalus barahonensis barahonensis (Tropiduridae) is a xerophilic to mesophilic species of moderate size (Schwartz and Henderson 1991). This generalist/opportunist consumer (Micco et. al. 1997 [1998]) was common all over the island, especially on the beach, where it probably was taking advantage of arthropods associated with human refuse. *Aristelliger expectatus* (Gekkonidae) is a small, xerophilic species often associated with trees (Schwartz and Henderson 1991). A number of individuals were observed under the loose bark of stumps and fallen trees. *Anolis brevirostris wetmorei* (Polychrotidae) is a sun-tolerant trunk anole (Williams

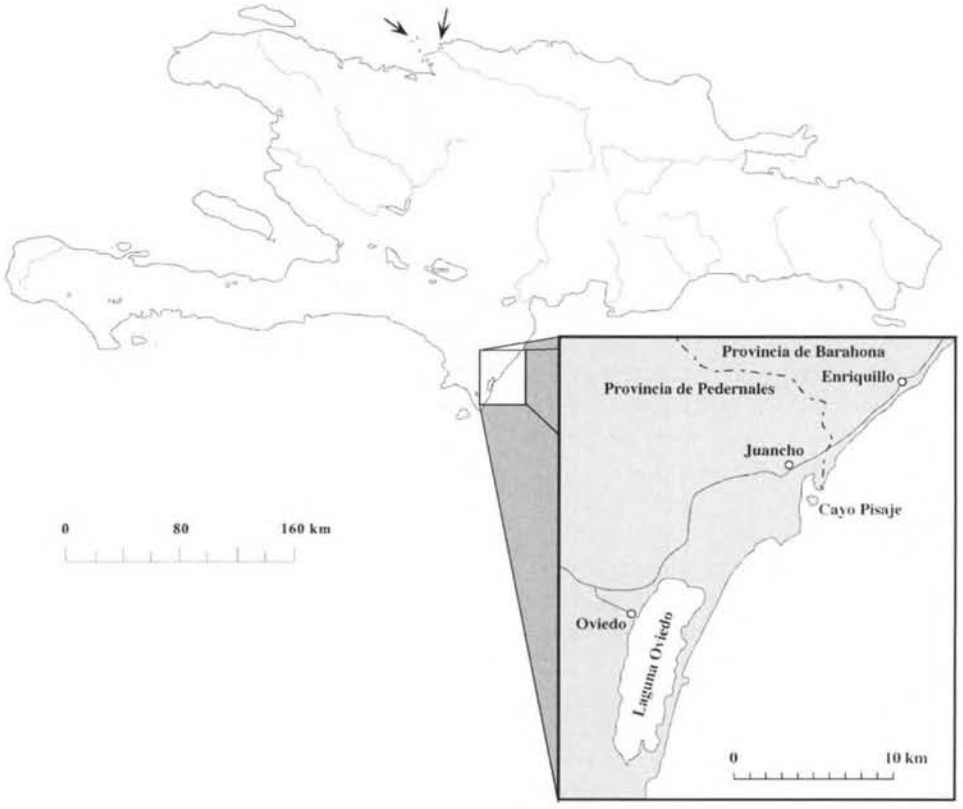

FIG. 1. Map of Hispaniola showing the location, size, and shape of Cayo Pisaje. Arrows indicate the locations of Isla Cabras and the Cayos Siete Hermanos (see also maps in Burns et al. 1992).

1983) adapted to xeric conditions (Schwartz and Henderson 1991). Anoles do not appear to be common on this island as only one specimen, a female, was found on a mangrove tree. *Sphaerodactylus randi strahmi* (Gekkonidae) is a xerophilic species, usually found beneath debris (Schwartz and Henderson 1991). Because this small, secretive species could have easily been overlooked, our failure to find any individuals should not be construed as an indication of its absence.

Island biodiversity tends to increase with size and decrease with spatial isolation (Brown and Lomolino 1988). Isla Cabras, off the northwestern coast of Monte Cristi Province, Dominican Republic, is about the same size as Cayo Pisaje and is almost twice as far from the mainland (Table 1). Equal size and closer proximity to the main island would suggest that Cayo Pisaje should support a greater biodiversity than Isla Cabras. However, Isla Cabras has six known species of lizards (Burns et al. 1992), whereas Cayo Pisaje has only four. Although all habitats present on Cayo Pisaje are also present on Isla Cabras, the topography of the two islands is very different. Isla Cabras has steep rocky slopes not present on Cayo Pisaje (Burns et al. 1992), and this greater topographical relief leads to different and more numerous microhabitats, allowing for greater biodiversity.

Although Cayo Pisaje is closer to the main island and equal in size to Isla Cabras, its species diversity is closer to that of some of the Cayos Siete Hermanos (Burns et al. 1992), seven small keys off the northwestern coast of Monte Cristi Province. Information regarding area, distance to main island, and number of species present on these islands is presented in Table 1. For each island, including Isla Cabras, area and distance to the main island were plotted against number of species in order to compare effects of island area and spatial isolation on species diversity (Fig. 2). Although species number was significantly correlated with distance (Kendall Correlation, $Z = -1.99$, $p = 0.05$), species number was not correlated significantly with area ($Z = -1.06$, $p = 0.29$). As we compared species diversity on these small Hispaniolan satellites, habitat heterogeneity and spatial isolation appear to have a greater effect on species number than area.

Each key of the Cayos Siete Hermanos is smaller and farther from the main island than Cayo Pisaje. Tercero has vertical structure and habitat complexity similar to Cayo Pisaje but is farther from the main island. Because distance was correlated with species number, greater spatial isolation would account for decreased faunal diversity. Arenas, Muertos, Ratas, and Tororú have less ver-

TABLE 1. Number of species recorded from Cayo Pisaje, Isla Cabras, and the Cayos Siete Hermanos along with area of each island and its distance to the main island.

Island	Area (km²)	Distance to main island (km)	Number of species
Cayo Pisaje	0.29	0.4	4
Isla Cabras	0.29	0.6	6
Arenas	0.04	14.8	0
Monte Chico	0.09	7.1	5
Monte Grande	0.12	10.0	5
Muertos	0.12	9.8	3
Ratas	0.13	11.3	1
Tercero	0.15	12.3	3
Tororú	0.12	6.0	3

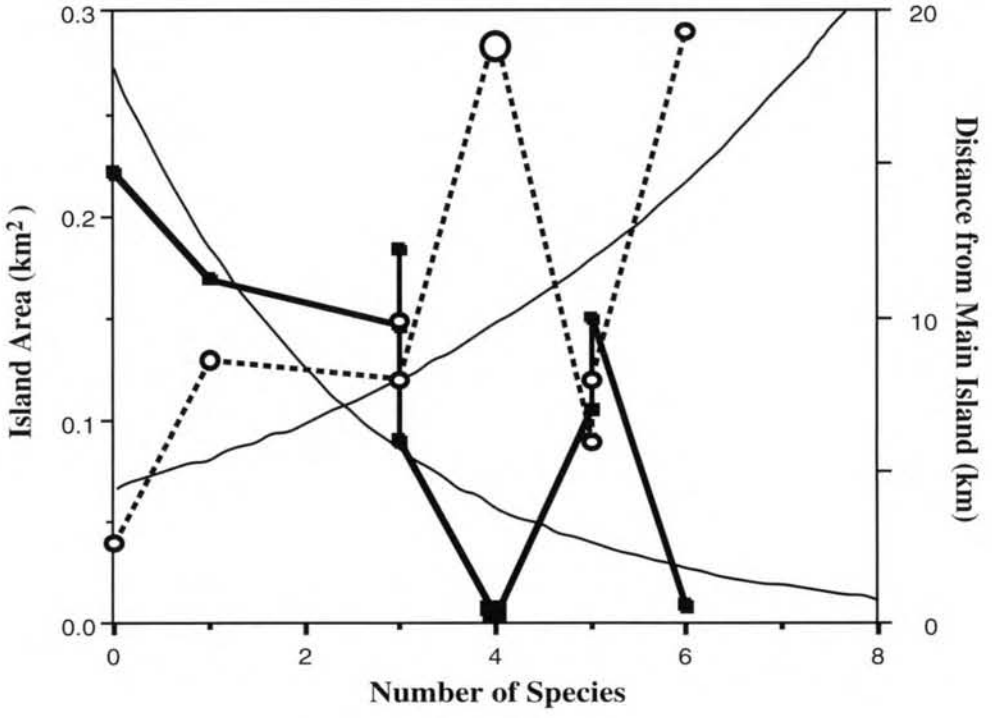

FIG. 2. Number of lizard species related to island area (dotted line) and distance from the main island (solid line) for Cayo Pisaje, Isla Cabras, and the Cayos Siete Hermanos, Hispaniola. Curve fits are exponential.

tical structure and/or less habitat heterogenity when compared with Cayo Pisaje, which may explain, along with the greater spatial isolation, the fewer species present on these keys.

Surprisingly, five species are present on both Monte Chico and Monte Grande (Burns et al. 1992). Unlike Isla Cabras, Monte Chico and Monte Grande are similar in topographical relief to Cayo Pisaje. In addition, sea grapes, present on Monte Grande, and arborescent scrub (predominately *Acacia*), present on Monte Chico (Burns et al. 1992), add a vertical dimension comparable to that of Cayo Pisaje. Because Monte Grande and Monte Chico are similar to Cayo Pisaje in topography and habitat heterogeneity and are smaller, the greater number of species on these keys compared to Cayo Pisaje contradicts the expected pattern.

Anolis cybotes cybotes, Ameiva chrysolaema ficta, Ameiva taeniura vulcanalis, Celestus costatus oreistes, and *Celestus curtissi aporus* are all ecological generalists present along the coast of the main island adjacent to Cayo Pisaje (Schwartz and Henderson 1991). That none has been recorded on Cayo Pisaje is surprising. *Anolis c. cybotes,* a heliophilic trunk-ground anole, requires vertical structure, such as that provided by mangroves and sea grapes, which are present on Cayo Pisaje. *Ameiva c. ficta* and *A. t. vulcanalis,* opportunistic foragers found sympatrically on the main island (Sprosten et al. 1999), can be found in habitats such as mangrove borders and scrublands (Schwartz and Henderson 1991), which are present on Cayo Pisaje. Debris along the beach seemed to be suitable habitat for either *Celestus c. oreistes* or *C. c. aporus* (Schwartz and Henderson 1991). Consequently, this key is seemingly capable of supporting at least some of these additional species, rendering its low diversity of lizard species all the more surprising.

Acknowledgments.—Barb L. Banbury, Elizabeth E. Cast, Matthew E. Gifford, Sonya E. Nelson, Laura Perdomo, Yanerys M. Ramos, Kimberly R. Schneider, and Roland A. Sosa helped in the field. José A. Ottenwalder, United Nations Development Programme, facilitated our opportunites for field research in the Dominican Republic. Permits were issued by the Departamento de Vida Silvestre and the Dirección Nacional de Parques, Dominican Republic. Fieldwork was supported by Grant No. DBI-9732257 awarded by the National Science Foundation to RP.

Several researchers (Durner and Gates 1993; Fitch 1963; McAllister 1995; Stickel and Cope 1947; Stickel et al. 1980; Weatherhead and Hoysak 1989) have examined home range size and habitat use patterns in black rat snakes (*Elaphe o. obsoleta*). Calculated home range sizes vary from 1.4 ha for females in a radio-telemetry study (Weatherhead and Hoysak 1989) to 28.3 ha for males in a mark-recapture study (Stickel et al. 1980). In spite of these data, home range estimates for other members within the genus are relatively scant. We examined movements of radio-telemetered gray rat snakes (*Elaphe obsoleta spiloides*) from both riparian and upland habitats along the northwestern extent of their geographic range. This report provides information concerning home range sizes, body temperatures recorded at time of relocation, and general patterns of habitat use at each of the study sites. Gray rat snakes have a narrow area of sympatry with black rat snakes (Ernst and Barbour 1989); as such, we also discuss briefly our findings relative to those reported for black rat snakes in similar habitats.

Adult gray rat snakes (three females and eight males) were collected from four forested sites in Shelby County, Tennessee, and from a 1500-ha bottomland hardwood site in the White River National Wildlife Refuge (WRNWR), Arkansas County, Arkansas, USA. The sites in Shelby County ranged between 124.7 and 251.2 ha and patches of old field habitat were present at each site. Subjects were returned to the laboratory for snout–vent length (SVL; ± 0.5 cm) measurement, and sex determination (cloacal probe). Transmitters weighing less than 5% of snake body mass (L.L. Electronics model LF1-11357-RS-T) were implanted into the peritoneal cavity of each subject using procedures modified from Wang et al. (1977) and Reinert and Cundall (1982). Following a minimum 3-day recovery period, subjects were released at the site of capture and relocated every 2 or 3 days thereafter (exception below). When relocations were separated by shorter time intervals (e.g., every 24 h), change in subject position was infrequently observed (pers. obs.).

TABLE 1. Sex, locality, home range size (ha, estimated using minimum convex polygon method), inclusive tracking dates, and summary data for gray rat snakes (*Elaphe obsoleta spiloides*) radio-telemetered in two different habitats. Shelby = localities within Shelby County, Tennessee; WRNWR = White River National Wildlife Refuge, Arkansas.

Snake #	sex (M/F)	locality	home range (ha)	tracking dates
15	M	Shelby	13.4	22 Oct 1994 – 14 Jun 1995
20	M	Shelby	0.4	22 Oct 1994 – 16 Apr 1995
27	F	Shelby	1.3	13 May 1997 – 24 Jul 1997
34	M	Shelby	1.8	13 May 1997 – 28 Jul 1997
36	F	WRNWR	5.3	20 Apr 1997 – 13 Jul 1997
37	M	WRNWR	6.8	20 Apr 1997 – 12 Jul 1997
38	M	WRNWR	4.8	5 May 1997 – 14 Jul 1997
40	M	Shelby	0.7	30 May 1997 – 17 Aug 1997
		Pooled home range data (mean ± 1 SE)		
All male subjects		—	6.3 ± 2.1	—
All female subjects		—	3.3 ± 1.9	—
All Shelby subjects		—	5.5 ± 2.7	—
All WRNWR subjects		—	5.6 ± 0.6	—

Two of the Shelby County snakes were telemetered between 22 October 1994 and 14 June 1995. The relocation interval for these individuals was extended to 2 weeks during their hibernation (2 December 1994 to 17 March 1995). Each hibernaculum was located within the area where the snake was radio-tracked during the activity season and snakes did not have separate winter and summer ranges; thus, home range estimates did not exclude movements to and from hibernacula (e.g., Brown and Parker 1976). All other subjects were telemetered between 2 April and 17 August 1997 and relocated at least once every 3 days. During 1997, we were unable to locate three snakes for more than 30 days following their release (possibly a result of transmitter failure, or predation on the subjects). Available data for these individuals underestimated their home range sizes (Rose 1982). Therefore, we excluded data from these subjects, leaving two females and six males for consideration in this study (see Table 1 for summary data).

Relocation sites for telemetered individuals in Shelby County (N = 5) were recorded with a global positioning system (GPS; hand-held Trimble units, accurate to ± 5 m). These relocation data were post-corrected using base station data from the University of Memphis Ground Water Institute (resulting in an accuracy of ± 5 m), and imported into CALHOME software (U.S. Fish and Wildlife Service, in collaboration with Microsoft, Inc., 1992). The relocation sites of the WRNWR snakes (N = 3) were plotted using measured distances and azimuth values from points on a 50 x 50 m grid that was established across a 50 ha study area as part of a separate project at that site (Wilson 1997). Home ranges for each subject were calculated using the minimum convex polygon procedure (MCP; Jennrich and Turner 1969) in CALHOME. Home range MCP estimates were used to facilitate comparison with other studies on rat snakes (Durner and Gates 1993; Weatherhead and Hoysak 1989), and also because of their use in other studies of reptilian spatial activity patterns (Gregory et al. 1987; Rose 1982). Furthermore, differences between home range sizes calculated using the MCP method and the harmonic mean method were absent (t- test; $p > 0.05$). Separate analyses of variance (ANOVA; $a = 0.05$) were used to determine if home range size differed by study site or tracking season. A low sample size of females (N = 2) precluded analysis of home range size as a function of sex. Differences in home range size as a function of SVL were determined using a Pearson's regression.

At the time of each relocation air temperature (± 0.2°C), cloud cover, and subject position were recorded. If the subject was visible, we also recorded substrate of subject's position (if arboreal, tree species and tree diameter at breast height [DBH, ± 0.5 cm] also were recorded), and subject activity. Subject concealment in arboreal habitats (positioned in a tree cavity or among vines) often prevented accurate measurement of subject height off forest floor. If the snake was accessible, cloacal temperature was obtained using a quick-reading thermometer (Miller & Weber, Inc.).

Sexes did not differ in size (mean SVL ± 1 SE equaled 120.9 ± 7.3 cm and 123.4 ± 8.1 cm for female and male individuals, respectively; unpaired t-test, $P > 0.05$), nor was there any relationship between individual size and home range size ($r^2 = 0.21$, $P = 0.25$, $N = 8$). The mean home range size equaled 5.6 ± 1.6 ha (range = 0.4–13.4 ha; Table 1); males had a mean home range size of 6.3 ± 2.1 ha, whereas females had a mean home range size of 3.3 ± 1.9 ha. Home range sizes did not vary as a function of study site ($F = 1.07$; $df = 3,4$; $P = 0.46$) or tracking season ($F = 0.21$; $df = 1,6$; $P = 0.66$).

Subjects were observed ascending into the arboreal habitat on five occasions and were positioned in the arboreal habitat 53.5 ± 11.9 % of all relocations (a grand mean of values for each snake). The DBH of the occupied trees averaged 40.4 ± 10.9 cm. Vines (e.g., *Toxicodendron* [poison ivy], *Vitis* [wild grape], *Parthenocissus* [Virginia creeper]) were present along the trunks of 84% of the trees occupied by snakes, but this value did not differ from the availability of vines on trees in either habitat (based on sampling of all trees within 10 m radius from relocation point; Chi-square test, $P > 0.05$). Use of the arboreal habitat was a function of the habitat in which the snakes were studied ($F = 29.2$; $df = 1,6$; $P = 0.002$); snakes in bottomland hardwood forest (WRNWR, N = 3) were relocated in arboreal habitat more often than snakes in upland forest sites (N = 5; 90.7 ± 2.3 % and 31.2 ± 8.2 % of relocations, respectively). Accessibility to subjects limited the number of occasions when cloacal temperature could be recorded; these values ranged between 17.8 and 36.6°C.

Although a low sample size precluded statistical verification of the results, the mean male home range size (6.3 ± 2.1 ha) was larger than that estimated for female subjects (3.3 ± 1.9 ha). Weatherhead and Hoysak (1989) reported that home range size for male black rat snakes in Ontario was over five times that of

females, and attributed the disparity to differences in activity associated with mate location (Gibbons and Semlitsch 1987; Gregory et al. 1987).

Several observations of predation by subjects occurred during the study. Snakes were recorded ingesting prey on two occasions (*Cardinalis cardinalis* [northern cardinal] nestlings and *Sigmodon hispidus* [cotton rat]). Following initial collection, one of the WRNWR subjects regurgitated three wood duck (*Aix sponsa*) eggs. Additionally, a regurgitated rock dove (*Columba livia*) hatchling was found within 3 m of the subject's position.

Gray rat snakes are known predators of arboreal nest contents (Jackson 1970, 1978; Mullin et al. 1998) and among North American *Elaphe*, tend to be more arboreal than other subspecies (Jackson 1976). Snakes in our study were positioned in arboreal settings in over half of the relocations. Peaks in breeding activity of many forest bird species overlap broadly between April and mid-June (Baker 1938). Thus, snakes remaining in the arboreal habitat throughout the bird breeding season may not experience any decline in prey availability while simultaneously avoiding their terrestrial predators. Snakes were observed in arboreal habitat as early as 20 March and as late as 21 November, but were relocated in this habitat type most often between 1 May and 15 June (56.0 % of relocations within that period).

Snakes in bottomland forests (WRNWR) were positioned in arboreal habitat more often than snakes in upland forests. Part of this discrepancy is a result of portions of the WRNWR site being flooded between March and late-May. Mean home range size for these snakes (5.6 ± 0.6 ha, N = 3) did not differ from the mean size estimate for subjects studied in the upland forest habitat (5.5 ± 2.7 ha, N = 5), suggesting that inundation of bottomland forest habitat does not restrict rat snake movements. Use of aquatic habitats during the activity season has also been shown in black rat snakes in Ontario (McAllister 1995).

The estimated home range size for gray rat snakes (5.6 ± 1.6 ha) fell within the range of home range sizes reported for a closely-related subspecies, the black rat snake. Home range sizes reported elsewhere for black rat snakes studied in a variety of habitats vary 20-fold (Durner and Gates 1993; Fitch 1963; Stickel et al. 1980; Weatherhead and Hoysak 1989). While some of this discrepancy could be attributed to differences in movement patterns associated with habitat or sex (Weatherhead and Hoysak 1989), the relocation method used may confound estimates of home range size. While we concede that our sample size is limited (possibly resulting in a lack of significance in our analyses), our home range estimates were similar to those of other researchers using radio-telemetry to relocate snakes. We suggest that the relatively large home range estimates based on mark-recapture methods (≥ 12 ha: Fitch 1963; Stickel et al. 1980) should be interpreted with caution because individuals cannot be relocated often enough during a single activity season (Madsen 1984; Rose 1982).

Acknowledgments:—We are grateful to J. Eubanks, D. Frederick, and G. Gale for assistance with various aspects of this study, and to the WRNWR staff for their cooperation. Comments from M. Keck, S. Kovac, S. Reichling, and three anonymous reviewers improved this manuscript. Partial funding was provided by a Sigma Xi Grant-in-Aid of Research, a challenge grant between the U.S. Fish & Wildlife Service and the University of Memphis, and the Biological Resources Division of the U.S. Geological Survey through the BBIRD program.

There are many inexpensive collecting techniques available to lizard biologists (Simmons 1987). The development of some of these techniques appears to have been driven by attempts to maximize catch rates of small to medium-sized cryptic, rare, or wary reptiles while minimizing specimen damage. Some of the most cost-effective collecting techniques, in terms of initial financial outlay, are noosing and projectiles (rubberbands and blowguns). However, these latter techniques occasionally mutilate specimens and cause injuries to live animals which may result in premature death. Recently, the mouse glue board (sticky trap), a technique touted as inexpensive, non-destructive, and non-lethal (Rodda et al. 1993; Whiting 1998), was introduced to the herpetological community as a sampling and censusing tool.

We collected a common south Texas lizard (*Anolis carolinensis*, Polychrotidae) via three collecting techniques (rubberband, noose, and sticky trap). We were interested in differences in fatality rates, if any, associated with the three techniques and, because *A. carolinensis* is territorial, differences in sex ratios of samples obtained via the three different techniques. Rubberbanding was accomplished using two #107 rubberbands tied together and stretched over the end of a wooden dowel rod to a premarked distance (50 cm). This was done in an attempt to standardize the impact force experienced by each lizard. Noosing was accomplished via 167.6 cm length fishing poles with monofilament nooses tied to the pole tips. Noosing and rubberbanding were done at a number of sites in the City of Kingsville, Kleberg County, Texas, USA. Sticky trapping was conducted using 20 Catchmaster® 13 x 21 cm Baited Mouse, Insect, & Snake Glue Boards (Atlantic Paste & Glue Co., Inc., 4-53rd Street, Brooklyn, New York 11232, USA) placed at irregular intervals in the backyard of a residence in Kingsville, Texas. Sticky traps were attached to the sides and tops of buildings, walls, and fences. Traps were checked every 15 min and after gentle removal from sticky traps, each lizard was placed in a plastic bag with several ml of canola oil facilitating removal of the adhesive (Bauer and Sadlier 1992). Collection of all lizards was completed within a two-week span (28 March–10 April 1998) and each collection technique was completed within a 24 h period. Diurnal temperatures during collection periods ranged from 27 to 35°C. After each collection, all lizards were transported to the laboratory, measured, sexed, and communally housed for one week in a covered 40-liter aquarium maintained at 25°C. Lizards were given water *ad libitum* and fed crickets *ad libitum* on days three and six of confinement. Surviving lizards were released on day eight at the approximate sites of collection.

There was a considerable difference in survivorship of lizards collected during this study. Deaths occurred during the week-long confinement period and not during collection. Rubberbanded lizards (N = 20) experienced a 25% fatality rate (5 dead). Sticky trapped lizards (N = 21) experienced a 47.6% fatality rate (10 dead). Sticky trapped lizards had a statistically higher fatality rate than did rubberbanded lizards (G_{adj} = 4.0348, 0.05>p>0.025). Noosed lizards (N = 26) experienced a 0% fatality rate. Sex ratios were also different for each of the collection techniques. Sex ratios of rubberbanded lizards were 15:5 (male:female), noosed lizards 22:4, and sticky trapped 11:10. Rubberbanded (G_{adj} = 6.399, 0.025>p>0.01) and noosed (G_{adj} = 15.5, p<0.001) lizards were significantly different from a 1:1 sex ratio. Sticky trapped lizards were not significantly different from a 1:1 sex ratio (G_{adj} = 1.902, 0.5>p>0.1). There was no significant difference in mean sizes of lizards captured via all three techniques ($MSD_{1,3}$ = 160.68; Sokal and Rohlf 1981).

Rodda et al. (1993) mentioned that not all lizards survived being removed from sticky traps followed by coating with cooking oil to remove the adhesive. Rodda et al. (1993) suggested these deaths from sticky trapping may have had a species-related component. All specimens of *Emoia atrocostata* (Scincidae, N = 54) collected by sticky trapping and included in Rodda et al. (1993) expired within 6 h of capture. Conversely, virtually all *Carlia* cf. *fusca* (Scincidae, N = 858) that were sticky trapped by Michael McCoid and included in Rodda et al. (1993) survived 4–8 h until deliberately sacrificed. Similar to *E. atrocostata*, our data suggest that a species of phylogenetically unrelated lizard (*A. carolinensis*) also does not respond well to sticky trapping.

These trapping events suggest that before a field project is begun, experimental trapping should be conducted. If population phenomena to be investigated require mark-recapture, then species-specific sensitivity to sticky trapping should be tested. If collection and preservation of all captured individuals is desired, then sticky trapping is probably the best unbiased collection technique available. In contrast, collection by the more sex-biased techniques of rubberbanding and noosing of territorial lizards might yield fewer fatalities during collection, but, because specimens are biased towards males, be less valuable in estimating certain population parameters.

In this article, we describe the construction of an enclosure specifically designed to study the thermal ecology of snakes. Though previous studies have used enclosures to examine ophidian thermoregulation (Dill 1972; Hammerson 1977, 1979, 1987, 1989; Johnson 1973; McGinnis and Moore 1969; Moore 1978; Osgood 1970; St. Girons 1975), few collected appropriate data to adequately address the effects of environmental variation on the behavior and consequent body temperature (T_b) variation of the animals (Charland 1995; Charland and Gregory 1990). To do so requires data on the limits of potential T_b's as set by the thermal environment, the actual T_b's of the animals, and their behaviors (Peterson et al. 1993; Stevenson 1985). The enclosure should ideally be large enough to offer a wide range of microhabitats and thermal environments. Our enclosure was designed so the T_b's of multiple animals, their thermal environments, and their behaviors could be monitored on a broader scale than that of previous studies.

We constructed the enclosure at the Savannah River Ecology Laboratory on the U.S. Department of Energy's Savannah River Site near Aiken, South Carolina, USA. The main function of the enclosure was to relate observed patterns of snake T_b variation to the thermal environment and behavior of the animals. We did this by designing the enclosure to combine natural habitat features with an automated monitoring system. We created habitat typically associated with southeastern species of semi-aquatic snakes by enclosing the area around an artificial pond and adding native plants, prey items, and retreats. The walls were constructed of 185 cm-high panels of cypress privacy fencing to which we mounted corrugated vinyl roofing. Sealing the seams between the overlapping sheets with siliconized acrylic latex caulking resulted in a smooth surface that the snakes were unable to climb. To further prevent escapes, we added a 50 cm-deep concrete barrier inside the base of the fence to exclude burrowing rodents (Fig. 1). The resulting fence enclosed a 20 x 30-m area around a 15 x 20-m plastic-lined pond. A spigot provided well water, and plugs spaced at vertical 50-cm intervals along a drainpipe located in the deepest part of the pond (2.5 m) controlled water depth. We covered the pond liner and banks with soil and leaf litter as a substrate for native aquatic and terrestrial vegetation. Animals added to the enclosure as prey included native fishes, amphibians, and snakes. Habitat within the enclosure was improved for both the prey species and the study animals through the addition of numerous retreats.

Retreats added in and around the pond included both natural and artificial structures. Natural structures consisting of brush tops and limbs were weighted and sunk in the pond for aquatic habitat or piled on the bank for semi-aquatic and terrestrial retreats. We constructed artificial dens for winter thermal ecology studies by simulating structures (e.g., rotting stumps or tunnels in banks) commonly used by local snakes for overwintering (Neill 1947,1948). For stumps, we buried 14 wooden barrels (each with a 10-cm hole in the top and filled with a leaf/ wood chips mixture) to a depth of 75 cm with 35 cm above the ground (Fig. 1). We made 14 tunnels by placing cypress boards in the bottoms of trenches in the pond bank and back-filling. During construction of the tunnel and stump dens, we added thermocouples to each so that the only available winter retreats were thermally monitored. We placed one thermocouple in the deepest part, middle, and top of each stump. Each tunnel den was similarly monitored with a thermocouple in the entrance and in the deepest end (Fig. 1).

We continuously monitored snake T_b's with an automated data acquisition system that combined a datalogger with radiotelemetry equipment (Peterson 1987; Peterson and Dorcas 1992; Peterson et al. 1993). The datalogger also measured operative environmental temperatures (T_e's) from the den thermocouples and from operative models (Bakken and Gates 1975; Peterson et al. 1993). By combining T_b, T_e, and observational data, we could determine the thermal consequences of behavior and microhabitat selection by each snake. An example is illustrated by graphing a sample of T_b and T_e data for a cottonmouth (*Agkistrodon piscivorus*) using a tunnel den in the enclosure (Fig. 1, inset). The snake was radiotelemetrically located in the retreat at 0830 h on 07 Dec 94 and was observed basking outside the tunnel at 1330 h. The graph shows the snake moving from the tunnel entrance deeper into the retreat around 0330 h and remaining there until emerging around 1015 h (Fig. 1, inset). Near 1700 h, it entered the retreat and slowly cooled until matching the tunnel temperature at 2130 h.

Enclosures present a level of inquiry intermediate between laboratory and field studies (Fitch 1987). Laboratory studies must often be conducted in unnatural settings, but have control over the number of variables, while field studies generally suffer the opposite problem. In field studies of thermal ecology, adequately characterizing the thermal environment in all possible microhabitats can be difficult if not impossible (Peterson at al. 1993). Our retreats were monitored better than can be accomplished in the field, and the main advantage of our enclosure is that its size allows a wide range of thermal options among and within retreat types. The significance of this is illustrated by translating 24-hr T_b into metabolic expenditures (Blem and Blem 1990) for snakes using different potential thermoregulatory strategies. For example, on the day shown in Fig. 1, a 600 g cottonmouth acclimated to 22°C seeking to maximize T_b by remaining in the warmest retreat would have a 24-h average T_b ($T_{b\,avg}$) of 23.5°C, representing a metabolic expenditure of 17.9 KJ. But by doing so, it would have expended 57% more energy than had it sought to minimize T_b in the coolest retreat, where its 24-h $T_{b\,avg}$ would have been 13.7°C with a metabolic expenditure of only 11.4 KJ. By continuously measuring T_b over the course of a winter, energy usage estimates could be compared to mass changes observed in the animals.

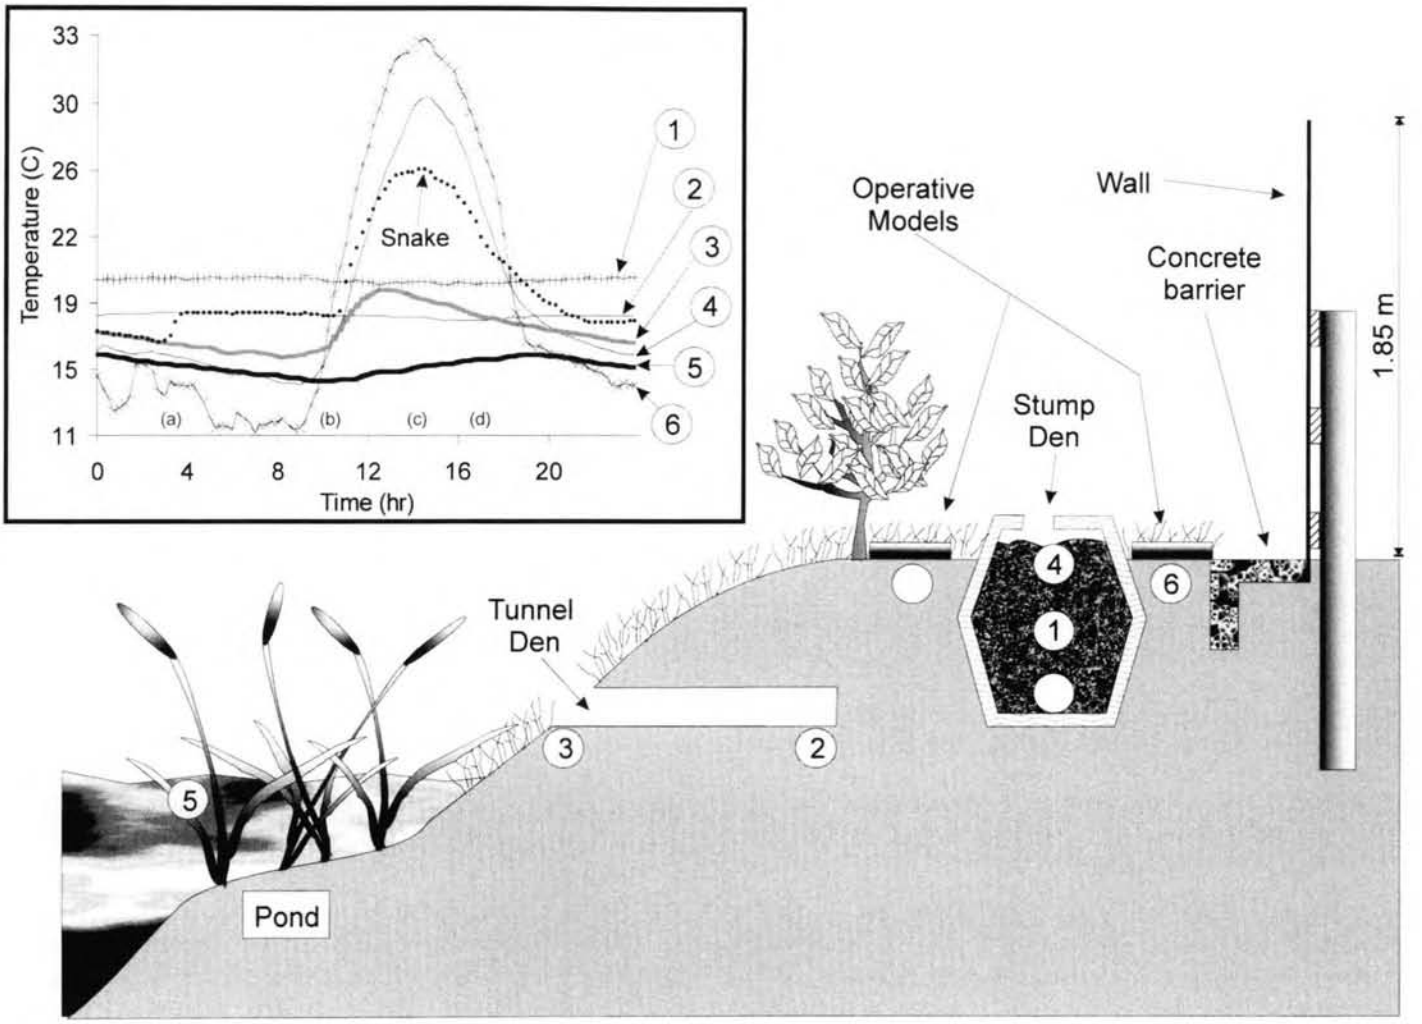

FIG. 1. Schematic diagram of the SREL snake enclosure showing a cross section of the wall and den construction. Numbered thermocouple locations correspond to numbered lines on the inset 24-hour plot. Data for the unnumbered thermocouples were omitted from the inset for clarity. Data for the inset were from 7 December 1994 for a tunnel den occupied by a 820 g cottonmouth (*Agkistrodon piscivorus*). Stump den data were taken from the retreat nearest to the snake's tunnel. Letters on the inset plot correspond to times at which the snake (a) moved deeper into the retreat, (b) emerged from the tunnel, (c) was observed basking, and (d) entered the retreat.

Continuous monitoring of multiple animals in an enclosure allows for the generation of field-testable predictions on the effects of the interaction between environment and behavior on T_b. Additionally, the completeness with which we can characterize both the aboveground and subterranean thermal environments allows for direct hypothesis testing. Such potential studies could include the role of temperature on habitat selection, activity times, foraging behavior, mating behavior, etc. However, intended studies must allow for the potential behavioral artifacts due to an enclosure being smaller than the active season home range for the species in question. We feel the size of our enclosure is adequate for exploring behavior outside of the active season for larger snake species (e.g., *Nerodia* spp.), and may be of use for active season work with smaller snakes, such as *Seminatrix*. Thus far, our enclosure has been used to associate specific patterns of T_b variation with overwintering behavior in cottonmouths (Lee 1996). Combining this knowledge with patterns of T_b variation collected from free-ranging cottonmouths permitted determination of the effects of environmental variation on the expression of various behaviors in the field. Though designed primarily to study overwintering thermal ecology, other potential uses for such an enclosure include studies of foraging ecology, species interactions/competition, mating behavior, and reproduction (e.g., multiple paternity, sexual selection, life history characteristics, etc.).

Acknowledgments.—We thank J. Whitfield Gibbons for support and guidance for this project. We are also grateful to the staff, technicians, and students at SREL who helped with construction and instrumentation of the enclosure. Charles R. Peterson provided many helpful comments on the manuscript. This project was made possible by Contract DE-AC09-76SROO-819 between the U.S. Department of Energy and The University of Georgia's Savannah River Ecology Laboratory and with Financial Assistance Award Number DE-FC09-96SR18546 from the U.S. Department of Energy to The University of Georgia Research Foundation.

Comparison of Two Radio Transmitter Attachments on Columbia Spotted Frogs (*Rana luteiventris*)

EVELYN L. BULL
Pacific Northwest Research Station
Forestry and Range Sciences Laboratory, 1401 Gekeler Lane
La Grande, Oregon 97850, USA
e-mail: ebull/r6pnw_lagrande@fs.fed.us

Radio telemetry permits determination of critical aspects of anuran ecology, such as summer movements and overwintering behavior, which would otherwise be difficult to study. However, the sensitive, moist skin of frogs prevents direct attachment of transmitters to the skin. Alternatives such as implantation (Werner 1991), ingestion (Oldham and Swan 1992), and attachment with external harnesses have been investigated with amphibians (Richards et al. 1994; van Nuland and Claus 1981). Implantation has been used successfully with toads but has limited application to frogs because of their thinner skin (Werner 1991). The limitations of this method include trauma, reduced activity, and infection (Oldham and Swan 1992). Ingestion of transmitters eliminates the need for an incision and the risk of infection, yet transmitters are frequently rejected by the animals (*Bufo bufo* and *Rana temporaria*; Oldham and Swan 1992).

A variety of external harnesses have been tested. Van Nuland and Claus (1981) used an external harness made of latex on *Bufo bufo*. However, toads were able to escape from the harness, particularly in water (van Gelder et al. 1986), and the harness caused skin irritations if not fitted properly. Another method of external attachment involved sewing a piece of Velcro to the dorsum of *R. palustris* (Johnson 1984). This method caused bacterial/fungal infections under the Velcro patch when used on *B. americanus* (Werner 1991). Rathbun and Murphey (1996) attached transmitters to California red-legged frogs (*R. aurora draytonii*) with a waist-belt made of aluminum balls. Although this method was successful some of the time, they experienced radio-belt loss and frog mortality from entanglement with vegetation. Peter Ritson and David Pilliod (pers. comm.) developed another waist-belt method using a satin ribbon fastened around the waist of adult Oregon spotted (*R. pretiosa*) and Columbia spotted (*R. luteiventris*) frogs, but they encountered problems with abrasions and entanglement with vegetation with this attachment.

Robustly gravid females are a particular challenge to track because transmitters attached with waist-band type harnesses are shed around the time of oviposition. The ability to tag females just prior to oviposition is important because females are typically easily encountered only in early spring before or during amplexus at oviposition sites. After egg deposition, they usually leave the oviposition site and are frequently difficult to locate. This difficulty led me to compare waist-band versus arm-band methods of transmitter attachment using Columbia spotted frogs and to examine the relative effectiveness of each for tracking gravid frogs in the spring and non-gravid frogs in the summer and fall.

Transmitters (model BD2, Holohil Systems Ltd., 112 John Cavanagh Rd., Carp, Ontario, Canada KOA 1L0, tel. 613/839-

0676) weighed 1.8 g and had a life of 6 months with a range of about 200 m. Transmitters represented about 2–5% of female and 3–8% of male body weight. Frogs were radio-tagged in seven breeding ponds and along the river in the Grande Ronde River watershed (Union County, Oregon, USA). The river lacked aquatic vegetation, while vegetation at six of the ponds was predominantly duckweed (*Lemna minor*). One pond contained pondweed (*Potamogeton* sp.), cattails (*Typhia latifolia*), and spike-rush (*Eleocharis palustris*).

The waist-band attachment was a satin ribbon (6 mm wide) with the transmitter glued (cyanoacrylate superglue) to the ribbon. The ribbon was adjusted around the abdomen, tight enough to prevent it from slipping over the hind legs. The ribbon ends were stitched together with carpet thread (cotton-coated polyester).

The arm-band method involved tying the transmitter around the upper arm of the frog with carpet thread (Fig. 1). Thread was inserted through the transmitter tunnel, and the ends were tied in a square knot on top of the transmitter. The loose ends were then tied around the upper arm of the frog using a square knot and a half hitch. A drop of glue was put on the knot to secure it, being careful to avoid contact with the frog's skin. Adjustment of thread tightness around the upper arm was critical. The thread was tight enough to prevent slipping over the elbow joint, yet loose enough to allow circulation. The forearm diameter is larger than that of the upper arm, so transmitters may remain on the forearm even if they slip over the elbow. One person can apply either attachment method in about 5–10 minutes.

I compared the two methods on robustly gravid females by radio-tagging six females with waist-bands and nine females with arm-bands in April and May 1998. In June 1998, arm-bands were put on two males and three non-gravid females. Waist-bands were put on 15 males and 17 non-gravid females radio-tagged in April and May 1998, and on six males and 13 non-gravid females radio-tagged in August and September 1998.

Radio-tagged frogs were located with a portable TR4 receiver and hand-held antenna (Telonics, Mesa, Arizona 85204, USA). When possible, gravid females were located one day after attachment of transmitters and every 3–5 days thereafter until egg deposition. To reduce abrasion risk, arm-bands were replaced with waist-bands as soon as possible following oviposition. I attempted to capture all non-gravid frogs every 2–4 weeks from May until December to check for abrasions. However, most frogs were inaccessible after October because ponds were frozen or frogs were overwintering underground.

Eighty-nine percent of gravid females with arm-band attachments retained them, compared to only 17% of those with waist-band attachments. No abrasions were observed with either technique, but arm-bands were kept on frogs only 1–15 days (mean = 5 days). The one waist-band attachment that was retained was tightened after one day and remained on the frog for more than a month.

There was 100% retention of arm-band attachments on males and non-gravid females, but all frogs developed severe abrasions through the muscle on the upper arm from the thread. Frogs carried these transmitters between 11 and 59 days (mean = 30 days). The upper arm on the frog captured after 59 days had healed over completely with the muscle enclosing the thread. The upper arm muscle of another frog, captured 31 days after the arm-band was removed, was healed and functional.

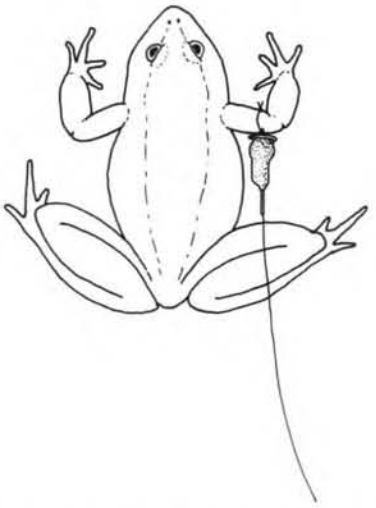

FIG. 1. Transmitter attached to the upper arm of a Columbia spotted frog.

Waist-bands were retained by 67% of frogs (10 males and 11 non-gravid females) radio-tagged in April and May. I recovered slipped harnesses and transmitters for the remainder (5 males and 6 females) and assumed that the frogs either slipped out of the harness or were depredated. Of the 21 frogs that were monitored for 18–126 days between May and August, about half had abrasions around the waist. The abrasions were in the subcutaneous layer or in the underlying muscle. Incidence of abrasion was higher on males (70%) than on females (27%).

Eighty-nine percent (6 males and 11 non-gravid females) of the waist-bands applied in August and September remained on the frogs. These frogs were monitored for 27–77 days and recaptured once or twice. Twenty-one percent had deep abrasions extending into the muscle, and an additional 16% had slight abrasions on the skin surface. The slight abrasions healed within two weeks after applying Neosporin and trimming the harness to about half the normal width.

Transmitters with arm-band attachments stayed on all but one frog. Arm-bands attached in April and May caused no injuries, but all arm-bands attached in June caused severe abrasions on the upper arm. I suspect abrasions on frogs in June and July were the result of the longer arm-band wear time and increased frog activity. Frog skin may also change physiologically with water temperature, phenology, or activity levels, making it more susceptible to abrasions. As a consequence, I believe the arm-band attachment is appropriate to use on gravid females in the spring for up to a week.

The high rate of loss of waist-band attachments from robustly gravid females was striking. Females about ready to deposit eggs may be severely hampered during egg-laying with a waist-band attachment, which essentially surrounds the tube through which eggs must pass. Waist-bands may be shed prior to oviposition, or the reduced girth of the female after oviposition allows the waist-band to easily slip off.

Other investigators have reported transmitter entanglement with vegetation as a problem, but I observed few instances of entanglement and none to which mortality could be attributed. Rathbun and Murphey (1996), using the ball-chain band, encountered mortality in dense, large bulrushes during its growth phase. Entangle-

ment with vegetation also has been observed with the satin-ribbon band (M. P. Hayes and K. R. McAllister, pers. comm). Differences among studies may reflect the risks posed by different types of vegetation. All but one of my study sites had limited vegetation besides duckweed.

Both techniques described here have limitations, but the advantage of the arm-band attachment clearly lies with gravid females for which waist-band options probably interfere with oviposition. Since abrasion with the arm-band technique can occur rapidly, I recommend application of this technique for intervals no longer than a week. As such, the arm-band technique is probably best applied to females of explosive breeding anurans, which generally oviposit with a high degree of synchrony over a few days. Waist-band attachments appear less likely to induce abrasions and thus remain the preferred class of attachment techniques for non-gravid females. However, abrasion risk with the waist-band attachment is significant over long time intervals, and application of this technique should be done only where relatively frequent inspection (weekly) of frogs is possible.

Acknowledgments.—Peter Ritson and David Pilliod provided information on radio-tagging frogs. Don Ashton, Marc Hayes, Kelly McAllister, David Pilliod, and Peter Ritson reviewed an earlier draft of this manuscript. Janet Hohmann sketched the arm-band attachment.

Captive rearing and translocation have been discussed as management tools in the recovery of the natterjack toad (*B. calamita*), common frog (*Rana temporaria*), common toad (*B. bufo*), and boreal toad (*B. boreas*)(Cooke and Oldham 1995; Denton et al. 1997; and Loeffler 1998, respectively). Translocation is fraught with many concerns and difficulties (Dodd and Seigel 1991), foremost among these is determining the survival rate of released individuals. To estimate survival, long term monitoring is necessary (Dodd and Seigel 1991) as well as the availability of a reliable method with which to mark individuals before translocation or release (Burnham et al. 1987). Marking allows the translocated individuals to be distinguished from a resident population or potential emigrants, and allows recaptures to be assigned to a particular experimental treatment or cohort release.

Current methods for marking amphibians require the handling of each individual. Toe clipping (Donnelly et al. 1994; van Gelder and Strijbosch 1996) and PIT tags (Brown 1997; Corn et al. 1997) have been used to effectively mark adult anurans, but these techniques are ill-suited for new metamorphs. Metamorphs are too small to receive implanted PIT tags, and toe clipping is labor intensive, difficult to perform and can be injurious to small animals. Additionally, young anurans may partially regenerate clipped toes (e.g., *Bufo boreas*, C. Carey and K. Scherff-Norris, pers. comm.), causing identification errors. Fluorescent dye has been used to mark small amphibians with limited success (Schlaepfer 1998). Recently, fluorescent dye has been mixed with semi-liquid elastomer and then injected under the skin of several amphibians, successfully marking them (Anholt et al. 1998; Woolley 1973; Davis and Ovaska 1998). However, amphibian reintroduction may involve thousands of individuals, reducing the feasibility of a mark which must be delivered individually. A batch marking method is needed that allows released individuals to be identified at least until they attain a size where, upon recapture, adult marking methods can be applied.

Tetracycline has been used to batch mark hatchery-reared fish by immersion bath, through diet or by injection (Peterson and Carline 1996; Unkenholz et al. 1997; Weber and Ridgeway 1967). Tetracycline deposition in bone matrix follows the pattern of new mineralization (Frost 1969; Recker 1983) providing a label which can be seen with fluorescent microscopy (Frost 1969; Minaire et al. 1974; Recker 1983). Weber and Ridgeway (1967) determined that low doses of tetracycline caused little distress or damage to

fish. Unkenholz (1997) reported <1% mortality in perch fingerlings immersed in oxytetracycline solutions of 309–748 mg/L. The first studies to use tetracycline labeling in amphibians were by Smirina (1972) and Francillon (1979, 1980) on *Rana temporaria* and *Triturus cristatus cristatus*, respectively. The use of tetracycline in amphibians and reptiles was reviewed by Frazier (1985a).

The effectiveness of tetracycline batch marking in fish and the high permeability of amphibian skin led us to evaluate the efficacy of oxytetracycline for batch marking young boreal toads. Oxytetracycline was chosen because of its recent, successful use in marking experiments (e.g., Unkenholz et al. 1997). Additionally, oxytetracycline has a low systemic toxicity (Suzuki and Mathews 1966; Weber and Ridgeway 1967), no "local effect on calcification" (Suzuki and Mathews 1966), and has a high intensity of fluorescence (Saxen 1969). Tetracycline markers have been used in rabies vaccinations and are acceptable in the food animal industry (L. Wolfe, DVM, pers. comm.).While the use of tetracycline ultimately requires a toe clip to read the mark, adult animals often are toe clipped as part of mark–recapture population studies (Donnelly et al. 1994). Handling stress and toe regeneration are presumably reduced in the larger adults and the excised toes would be available to determine the presence or absence of a batch mark.

Boreal toadlets were reared in captivity at the Research Fish Hatchery in Bellvue, Colorado by the Colorado Division of Wildlife from eggs collected in Clear Creek County, Colorado, USA (UTM: Zone 13, 429324 E, 4402598 N). Tadpoles and toadlets were maintained in outside raceways. Sixty, approximately three-month old toadlets were selected randomly from the raceway. Toadlets were weighed to the nearest 0.01 g and assigned randomly to one of six treatments (Table 1).

Oxytetracycline HCL (OXY-TET® 100, Anchor Division Boehringer Ingelheim Animal Health Inc., St. Joseph, Missouri, USA) baths (5–15 mm deep) of three concentrations were prepared using filtered water in clean plastic containers with ventilated lids. Toadlets were placed in the baths and left undisturbed in an environmental chamber (6 or 24 h).

After the baths, toadlets were rinsed with filtered water and placed in corresponding aquaria. Clean aquaria (45.5 L) were furnished with a layer of aquarium gravel (rinsed twice with filtered water), a layer of plastic lighting grating (approximately 10 mm x 10 mm mesh, washed with mild detergent and chlorine bleach, rinsed in filtered water and dried), and a layer of sheet moss. Filtered water was added to the level of the grating. A moisture gradient was provided by slightly elevating the substrate at one end. Toadlets were fed 5 d per wk on live, first-instar crickets dusted with Reptavite® vitamin powder. Water was changed once per month for the first month and once per wk thereafter. Moss was changed once per month and aquaria were misted occasionally with filtered water. Aquaria were kept in an environmental chamber for the entire 24 wk experiment (12 h:12 h light:dark cycle; 22°C during light and 15°C during dark; humidity: 96.6 ± 0.1%). The position of the aquaria in the environmental chamber was randomized and rotated each week.

After 24 weeks, the 3rd toe on the left front foot and the 2nd toe on the right hind foot were removed (Donnelly et al. 1994) from each toadlet, placed in ethyl alcohol, and kept in opaque containers. If toadlets died before the end of the experiment, toes were collected and analyzed. Only data from front toes were used in the analyses, except where data were missing due to difficulties in histological preparation (N = 6). In these cases, data from a hind toe were substituted.

Toes were processed using a methyl methacrylate method for calcified bone (Aquino, unpubl.; Ruhl-Fehlert and Ludl 1987; Sanderson et al. 1990). Methacrylate blocks were cut to approximately 1 x 1 cm squares. The side containing the bone was ground by sanding belt and by hand (wet grinding paper P800 and P1000) until a clear cross section of bone was visible on a 20x microscope. Each sample was numbered and placed in a small, opaque envelope.

Samples were examined under a Leitz microscope (36x) with a 100 W mercury source (Short Arc Lamp Power Supply, E. Leitz Co. Rockleigh, New Jersey, USA) using 400–440 (blue violet) excitor filter with a 470 barrier filter. Samples were scored and assigned numeric values as follows: 5) very good label; 4) good label; 3) poor label; 2) ambiguous fluorescence, unknown if label or autofluorescence; 1) no fluorescence or autofluorescence, bluish and diffuse; or 0) missing samples. Scoring was based on brightness and color. All samples were randomized and then examined "blind"; the scorer (EM) did not know which block or treatment she was examining. Data were analyzed using ordinal logistic regression (Agresti 1996) under a proportional odds model (SAS 1989). A design matrix was supplied to account for the categorical nature of the treatments (see, for example SAS 1989:1099–1101). Significance levels were set at 0.05 for single comparisons and 0.006 (corrected using the Bonferroni method) for multiple comparisons.

Initial masses of toadlets in the 6 treatments were not different (Table 1; $F_{5,54} = 0.270$, $P = 0.927$). Growth during the experiment was uniform among treatments; the final masses averaged at least three times the starting masses and were not different among treatments ($F_{4,43} = 0.573$, $P = 0.683$).

All the toadlets in treatment 2 died in February, probably due to a buildup of ammonia in the tank. We tested the water in all the tanks for ammonia (Jr. Ammonia Water Test Kit®, Wardley Corporation, Secauscus, New Jersey, USA). The test indicated ammonia levels in excess of 5.0 mg/L in the treatment 2 aquarium.

TABLE 1. List of treatments and mean mass of toadlets present at the start and end of experiment. * Approximate mass at death after 11 wks of treatment.

	Mean mass of toadlets (S.E., N)	
Treatment	Start	End
1) Control A: 6 h filtered water	0.69 (0.07, 10)	2.61 (0.22)
2) 6 h oxytetracycline (1000 mg/L)	0.80 (0.07, 10)	0.77 (0.08)*
3) Control B: 24 h filtered water	0.71 (0.12, 10)	2.37 (0.23)
4) 24 h oxytetracycline (250 mg/L)	0.72 (0.05, 10)	2.23 (0.16)
5) 24 h oxytetracycline (500 mg/L)	0.75 (0.08, 10)	2.37 (0.13)
6) 24 h oxytetracycline (1000 mg/L)	0.74 (0.07, 10)	2.32 (0.18)

The other aquaria had ammonia levels (≤ 0.25 mg/ L). Toadlets were frozen at death and later thawed, blotted dry, and weighed. One toadlet in controls 1 and 3 also died in February. These were the smallest animals and may have starved.

Bone sections of toadlets exposed to tetracycline usually (36/39 = 92%) had distinguishable fluorescent labels (Figs. 1 and 2). Neither tetracycline concentration nor exposure time influenced the detectability or brightness of the label ($P \geq 0.038$). Control A (6 h) differed significantly from treatment 2 (6 h; $\chi_1^2 = 5.60$, $P = 0.018$), control B (24 h) differed significantly from treatments 4, 5, and 6 ($P \leq 0.002$), and control A (6 h) did not differ from control B (24 h; $\chi_1^2 = 2.57$, $P = 0.108$; Table 2).

Autofluorescence was a significant problem. In 3 of 39 treated samples, we were unable to determine whether the fluorescence resulted from the label or autofluorescence. Eleven of 20 control samples showed no fluorescence or only a diffuse, bluish glow indicating autofluorescence but in 9 of 20 control samples we observed fluorescence indistinguishable by eye from samples with labels. Three of the 9 fluorescing control samples and 3 of the clearly labeled samples were chosen at random, sectioned (10 µm), mounted, examined microscopically, and photographed. In sections of two control samples, the fluorescence appeared diffuse and bluish suggesting that the tissue was autofluorescing, but the third control section appeared to have a label. Color slides of these samples and the labeled samples revealed a difference between control bone and labeled bone, with all labeled specimens being distinctly more gold in color than the autofluorescence in the controls. One roll of film was used for all slides; the same exposure and ASA was used on all slides.

We found that oxytetracycline labeled the bones of soaked toadlets, but under low power magnification of the blocks, it was sometimes difficult to distinguish the yellow gold color of the oxytetracycline label from the natural, bluish-green, diffuse autofluorescence of the bone. These results, which agree with an experiment conducted concurrently on pickerel frogs (*Rana palustris*) and green frogs (*R. clamitans*) by Hatfield et al. (unpubl.), indicate that this method is not completely reliable.

Yellow green autofluorescence has been detected in turtles, but it was less intense and more diffuse than the label fluorescence at the line of active bone growth, where the label is expected (Frazier 1985b). In our study, neither oxytetracycline concentration nor length of treatment influenced the brightness of the label, contrary to Frazier's (1985a) findings. This may have been partly due to method. Frazier injected tetracycline whereas we soaked animals in a oxytetracycline solution. We soaked the toadlets in specific concentrations of oxytetracycline because toads absorb water readily through their skin and other methods of administration such as intramuscular, subcutaneous injection or oral dosing are problematic due to the size of the toadlet and the time necessary to handle thousands of animals. Although Milch et al. (1958) found no evidence that the route of administration affected the distribution of the label, the experimental toadlets were occasionally observed to place a limb on the side of the container, out of the solution. This may have affected the standardized uptake of the oxytetracycline and may have been related to the concentration of the solution. Hatfield et al. (unpubl.) found the soaking method to be ineffective. According to Milch et al. (1958) variation in fluorescence occurs between species and age in tetracycline labels.

FIG. 1. Cross section of phalange of boreal toadlet (24 h exposure in 1000mg/L tetracycline bath) viewed at 20x magnification under fluorescent light. Tetracycline label is visible as bright line in the cortex, below the periosteal layer, marrow tissue visible in center.

TABLE 2. Number of samples in each treatment for each label category: assigned ordinal values in brackets.

Treatment	N	very good label [5]	good label [4]	poor label [3]	auto- or label [2]	none or auto-fluorescence [1]	missing samples [0]
1) Control A: 6 h filtered water	10	0	0	0	6	4	0
2) 6 h oxytetracycline (1000 mg/L)	10	4	4	1	1	0	0
3) Control B: 24 h filtered water	10	0	0	0	3	7	0
4) 24 h oxytetracycline (250 mg/L)	10	6	2	1	0	0	1
5) 24 h oxytetracycline (500 mg/L)	10	0	7	2	1	0	0
6) 24 h oxytetracycline (1000 mg/L)	10	3	5	1	1	0	0

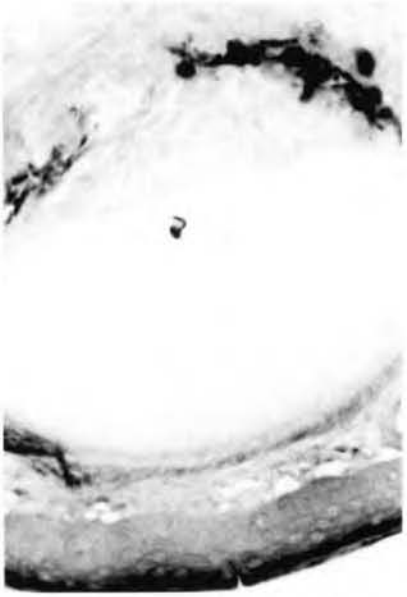

FIG. 2. Cross section of phalange of boreal toadlet (control, 24 h exposure in filtered water) viewed at 20x magnification. No tetracycline label visible.

The toadlets in this experiment were within 1 wk of the same age.

There may have been an aquarium effect as all toadlets in each treatment were housed in the same aquarium. However, we believe this possibility is minimized given our care in cleaning the aquaria before the experiment and our randomization of aquaria position during the experiment.

This method is impractical as a field tool for several reasons. First, the toe must be processed and viewed in the laboratory. This introduces complexity and considerable cost, especially because thin sections and photography may be necessary to distinguish between a labeled bone and an autofluorescing bone. Histological costs were US $850.00 (120 specimens) plus an additional cost of US $7.00 per slide for the thin sectioning. Microscope time and photography of the sections were donated by CSU. Treatment costs including aquaria set up, oxytetracycline, and food was approximately US $450.00.

Second and perhaps most importantly, marks may appear ambiguous; unmarked toads can easily be scored incorrectly as having been marked and marked toads may be scored as unmarked. This violates an important assumption in all capture-recapture models (Pollock et al. 1990). The overall mis-identification rate for microscopic (36x) examination was 20% (Table 2). Due to cost constraints, we applied additional identification methods (e.g., thin sectioning and photography) to a small subsample; three of the potentially mis-identified specimens and three of the labeled and correctly identified specimens. These methods allowed us to differentiate between label and autofluorescence and determine that the three mis-identified specimens were exhibiting autofluorescence. Unfortunately, these results cannot be extended beyond our study due to sample size.

Finally, the longevity of tetracycline labeling has not been tested in amphibians although tetracycline labeling in green turtles (*Chelonia mydas*) was evident one and three years after treatment for live and frozen specimens respectively (Frazier 1985b). Although we do not recommend this particular method of tetracycline marking, batch marking with an appropriate method (e.g., Taylor and Deegan 1982) is a sound technique to use with very small or juvenile anurans.

Acknowledgments.—We thank the Colorado Division of Wildlife, J. Goettl and K. Scherff-Norris for early tadpole and toadlet husbandry; L. Morgan and B. Dutton for help with toadlet husbandry; Colorado State University Pathology Department; R. Norrdin, R. Zink, C. Kerlee, and F. Aquino for assistance with the histological preparation and interpretation; J. Hatfield and P. Henry for discussions and commenting on previous drafts of the manuscript, B. Anholt and four anonymous reviewers for improvements to the manuscript. The use of toadlets for this experiment was approved by the Animal Care Committee at MESC.

Determining fractional composition of dietary items is necessary when developing a complete ecological inventory for a species. Techniques for gathering data on food habits of turtles include direct observation, examination of fecal material (Demuth and Buhlmann 1997), and collection of stomach contents (Legler 1977; Parmenter and Avery 1990). Examination of the digestive tract contents has advantages over other methods (Parmenter and Avery 1990)

As with other species (Demuth and Buhlmann 1997; Killebrew 1991), we experienced problems with the stomach flushing method in our dietary studies of the Texas river cooter (*Pseudemys texana*) and the red-eared slider (*Trachemys scripta elegans*). Problems encountered ranged from little or no contents obtained to serious internal damage to the turtles. Here we offer modifications to the stomach flushing technique which enhance its effectiveness.

Initially, we used a modification of Legler's technique and a restraining device similar to that described by Parmenter (1980). The restraining table (60 cm x 28 cm) was tilted at a 35 degree angle allowing gravity to facilitate the flow of contents from the stomach. A turtle was secured to the table with a web strap and a non-skid pad mounted on the table surface prevented the turtle from sliding out of the webbing. A hand operated fluid transfer pump, mounted on the side of a laboratory bench, supplied water for flushing through a small animal feeding tube (3.5 mm OD) (Fig. 1).

Difficulties were encountered when using a hook and cable apparatus (Parmenter 1980) to extend the neck and hold open the mouth of an agitated turtle. These included trauma to the jaws and palate. Additionally, rupture of the esophagus due to blockage by the flushing tube and food mass was noted in two post-procedural necropsies.

Administration of a tranquilizer, ketamine HCl, significantly reduced this problem. Ketamine HCl is a dissociative anesthetic (Bennett 1996) which is currently a federal schedule III drug requiring a prescription from a licensed veterinarian. Individuals were injected intramuscularly in the left forelimb with 25mg/kg ketamine HCl (Aiello 1998; Bennett 1996). The effect of the drug, evinced by total relaxation with head extended, was noted in 20 to 30 minutes. The sedated turtle was positioned (carapace down, head oriented downward) on the pad and the belt was tightened at mid-plastron. No hooks were required to extend the head or hold it in place. An adjustable buret clamp on a threaded rod mounted

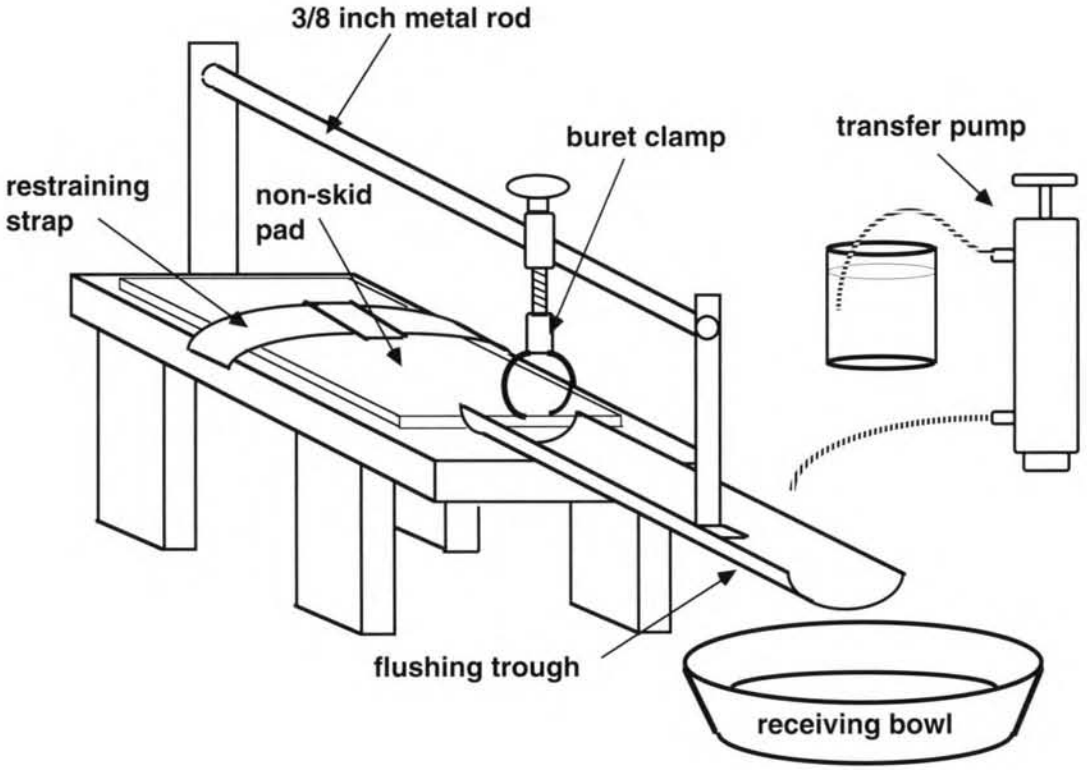

FIG. 1. Diagram of a table (60 cm x 20 cm) used in flushing turtle stomach contents for dietary analysis.

above the table surface secured the neck behind the skull (Fig. 1). The feeding tube was coated with lubricating jelly and slowly inserted into the esophagus (a small volume of water provided additional lubrication). Constant water pressure was maintained to prevent air from entering the tube. The cardiac sphincter relaxed under the influence of ketamine so that little resistance was felt until the tube reached the stomach. Occasionally, in the case of larger specimens, the turtle was turned head up, then down in an attempt to mobilize the stomach contents.

Our technique reduced stress and prevented damage to mouthparts. Relaxation of the digestive tract also reduced internal damage caused by attempting to force a tube through the closed cardiac sphincter or the inability to flush food past this sphincter resulting in a ruptured esophagus. Passage of food through the esophagus was eased by the relaxing effects of the ketamine and the percent rate of successful flushings increased. Stomach contents were collected from 79% of the turtles (N = 38) flushed after the introduction of ketamine compared to 38.5% (N = 39) before its use. Damage to the mouth, stomach, or esophagus, as indicated by blood, was also reduced from 30 turtles using hooks to one turtle after the introduction of ketamine.

If the receiving bowl filled with flushed water without any food items, the turtle's stomach was assumed to be empty. Stomach contents often existed in clumps that resisted passage through the esophagus with the tube in place. Because clots of vegetation were common and could be felt as an increase in pressure at the pump, care was exercised while flushing each turtle. After flushing, turtles were held 24 hours to allow recovery from the effects of anesthetic and to ascertain that no adverse reaction or physical damage occurred.

Turtles that could not be flushed immediately were placed in a refrigerator to slow their rate of digestion. Prior to flushing, each individual was removed from the refrigerator and allowed to warm to room temperature for approximately 20 minutes.

Stomach flushing has proven to be an effective method to study the food habits of turtles. Further improvements to the method are possible. Research into ketamine dosages and gravity flow methods could refine the technique.

A New Design for a Lightweight Squeeze Box for Snake Field Studies

Handling venomous snakes is an inherently dangerous task. To reduce the risk of snakebite, many methods of snake capture and handling, including the use of nooses, acrylic tubes, and snake tongs (Fitch 1987), have been suggested. There is, however, still the issue of safely obtaining measurement data on captured snakes. The squeeze box technique for obtaining morphological measurements of live snakes was first introduced by Quinn and Jones (1974). The squeeze box works by firmly holding a snake between a soft base (generally foamed rubber) and a plexiglass cover while measurements are made. The design of Quinn and Jones (1974) is quite useful in a laboratory setting; however, alterations were necessary for it to be useful in the field. My work on *Agkistrodon p. piscivorus* required an alternative design for a squeeze box. The new design is lightweight, easily carried or pulled through a research site, allows head and body measurements to be made, and permits the tail of the snake to be safely extracted for measurements, determination of sex, and ventral or subcaudal scale clipping.

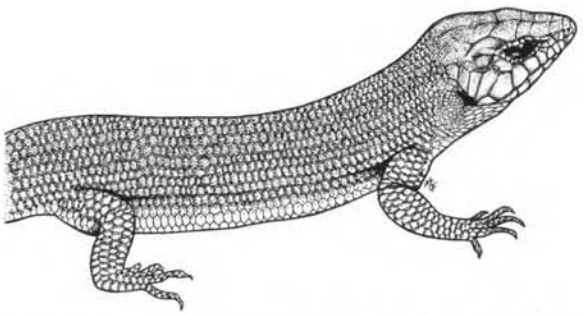
A plastic, rectangular storage container ("sweater box") approximately 85 cm long, 40 cm wide, and 15 cm deep was used for the body of the squeeze box. The top of the box was made from plexiglass (0.5 cm thickness). A plastic cabinet handle was bolted onto each end of the top to facilitate its removal and replacement. The bottom of the box was lined with 5 cm of foamed rubber. In each end of the container, a small porthole was cut to allow the extraction of the tail. One porthole was 2 cm in diameter, the other 3.5 cm—one for large snakes and one for small snakes. To prevent snakes from escaping through these openings, a sliding door was placed over each opening. The sliding doors were constructed from the same plexiglass as the top. Runners for the doors were constructed from plastic aquarium edging (readily available at most pet centers). A small knob was attached to each sliding door. A shoulder strap was bolted onto the device to allow the box to be easily carried. Due to the aquatic nature of the animals I studied, closed-cell foamed rubber flotation was attached to the bottom of the device so that it could be pulled through the water (Fig. 1).

As with the squeeze box of Quinn and Jones (1974), the total length of the animal is easily marked on the plexiglass lid along the midline of the snake using a grease pencil or water-based marker. Additionally, I marked head width and length on the plexiglass lid. The tail of the animal is easily extracted with a small noose constructed from string and a hollow tube. Tail length is determined directly by measurement (and subtracted from total length to obtain SVL), sex is easily determined, and scale-clipping is easily accomplished.

FIG. 1. A lightweight squeeze box for snake field studies. The plexiglass top, foamed rubber lining, portholes and their accompanying sliding doors, shoulder carrying strap, and closed-cell foam flotation attachments are visible. Design and dimensions are discussed in the text.

All measurements were taken with a flexible metric tape. Measurements (N = 10) taken in the field and then repeated in the laboratory on anesthetized animals differed by less than 1 cm for all morphological categories that I examined (total length, SVL, tail length, head width, and head length; Cross 1998), suggesting that this technique is adequate for most field studies.

This lightweight squeeze box is useful for field studies of snakes, particularly for venomous snakes where a researcher wishes to minimize direct handling of specimens. Additionally, the box can be easily modified to facilitate particular uses—such as the addition of backpack straps, or the removal of flotation devices.



Notice.—The research described here was developed by the author (CLC) prior to his employment with the U.S. Environmental Protection Agency's Office of Research and Development. The manuscript has been subjected to EPA's administrative review but the conclusions drawn are soley those of the author. Mention of trade names or commercial products does not constitute endorsement or recommendations by EPA for use.

Eumeces laticeps (Broad-headed Skink). Illustration by Michael G. Frick.

and often grasped fecal pellets in their jaws and repeatedly shook them. The hatchlings' interest in the fecal pellets gradually waned after 15 minutes, and by 20 minutes, the plate of dried feces was largely ignored. However, thirteen days later, a plate of dried feces was placed in the cage with the 7 Agua Caliente hatchlings. Two of the hatchlings again tried to eat the feces, but the others showed no interest.

TABLE 1. Food choice of hatchling chuckwallas.

Locality	(N)	Ate lettuce first	Ate feces first
Agua Caliente, AZ	(19)	4	15
Crater Range, AZ	(4)	0	4

Desert Center, CA	(9)	0	9
Palm Springs, CA	(5)	1	4
Totals		12	42

The feces of adult chuckwallas were generally too large for the hatchlings to ingest. However, the neonates seized the dried fecal droppings in their mouths, usually at the tapered ends of the pellets, attempted to bite them, and subsequently shook them violently. In some instances, this repeated shaking behavior (up to 8 bouts observed), successfully led to breaking off small bits of the fecal pellet which could be ingested. Whether ingestion of fecal material is necessary for inoculation of symbionts remains conjectural. Only a few hatchlings succeeded in actually eating bits of fecal material, but all lizards eventually demonstrated normal food digestion. Hence, the repeated "mouthing" of the fecal pellets was probably sufficient to inoculate the neonates with symbiotic microbes.

The gut symbionts of iguanas are obligate anaerobes and presumably do not survive long outside the intestinal environment. Thus, Troyer (1982) concluded that a brief association between juvenile and adult iguanas was necessary to effect microbial transfer. While the microbial symbionts in chuckwallas have not been studied, presumably they are also anaerobes. The strong social component to chuckwalla behavior (Berry 1974), would facilitate parent to offspring transfer (via coprophagy) of these colonic microbes.

Coprophagy was not observed during the subsequent months that the hatchlings were reared, except on two occasions. A juvenile was observed tongue-flicking and briefly "mouthing" a fecal pellet from a sibling that shared its cage, and another hatchling actually ate an entire fecal pellet. These instances occurred after a two-day period of food deprivation and may simply have been due to hunger.

Acknowledgments.—Chuckwallas were collected in California under scientific permit numbers 0301 and 9044, and in Arizona under several nonresident hunting licenses. I wish to thank Jay Chance, Jerrold J. and Martin J. Feldner, Tom Greb, Ellen M. Kiley (USFWS), Jim McGuire, Tony Mills, Lester Milroy III, Regis Opferman, and Jeff Wines for help in procuring adult chuckwallas. T. Greb assisted in recording observational data.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 20, Number 1 (March 1999).

CAUDATA

PLETHODON IDAHOENSIS (Coeur d'Alene Salamander) **SKELETAL ABNORMALITY.** Natural occurrence of scoliosis has been reported in *Plethodon glutinosus* (Marvin 1995. Herpetol. Rev. 26:30). Herein we report a similar condition in an adult male (4.2 cm SVL) *Plethodon idahoensis* collected in the Kootenai River Gorge, Lincoln Co., Montana, USA, on 30 May 1985. A radiograph of the individual (Fig. 1) reveals that trunk and anterior caudal vertebrae were affected. Opacities more dense than bone also appear in the trunk and may represent ingested mineral.

A comparison with cleared and stained *P. idahoensis* specimens indicates that this abnormal salamander's SVL would have exceeded 5 cm if not for the unusual spine curvature. The individual was therefore at least 4 yrs old when collected (Lynch 1984. Reproductive Ecology of *Plethodon idahoensis*. M.S. Thesis, University of Idaho, Moscow). Thanks to Chris Davitt for the radiograph and Dan Bivens for photography.

ANURA

BUFO SPECIOSUS (Texas Toad). **DIET.** Reports of food items for *Bufo speciosus* are nonexistent. However, like other xeric toad species, it is presumed to feed on a diverse array of terrestrial and flying arthropods (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.) On 7 August 1998 at ca. 0100 h, a subadult (54 mm SUL, 18.5

g) *B. speciosus* was collected alive on road (AOR) from Kerr County, Texas, USA, 10.6 rd km E of junction of US Hwy 83 and St Hwy 39, on St. Hwy 39. The stomach and intestines were removed and preserved in 70% ETOH the following day. Upon later examination, the following prey species were found, with number of individual prey items in parentheses. Hymenoptera: *Odontomachus clarus* (1), *Pogonomyrmex barbatus* (48), *Solenopsis invicta* (8); Coleoptera: *Agrypnus* sp. (2), *Harpalus* sp. (3); Hemiptera: *Cnemodus marvoritus* (1).

The *B. speciosus* specimen has been deposited in the Texas Cooperative Wildlife Collection, Texas A&M University, Department of Wildlife and Fisheries Sciences, College Station, Texas (TCWC 79864). Stomach contents were deposited in the Texas A&M University Insect Collection (TAMUIC 627), Department of Entomology, College Station, Texas. I thank Edward G. Riley, Department of Entomology, Texas A&M University, for correcting and verifying insect identifications.

HYLARANA ALBOLABRIS (NCN). **PREDATION.** In western Uganda, *Hylarana albolabris* (Ranidae) is found exclusively in waters with low dissolved oxygen, typically permanent pools and streams. Unlike most North American species (Wassersug and Seibert 1975. Copeia 1975:86–103), *H. albolabris* tadpoles begin air breathing immediately after hatching. This reliance on atmospheric air as a source of oxygen is no doubt requisite to their survival under extreme hypoxia. However, air breathing increases tadpole vulnerability to visual predators, such as turtles (Feder 1983. Physiol. Zool. 56:522–531). For air-breathing fish, wading birds are the dominant predators (Kramer 1987. Envir. Ecol. Fish 18:81–92), and they may also be important tadpole predators. *Hylarana albolabris* tadpoles possess seven discrete glandular regions that produce toxins which deter vertebrate predators (*Clarias* catfish and *Xenopus* frogs), but these glands seem to be ineffective against invertebrate predators.

During a field study of the ecology of *H. albolabris* tadpoles in Kibale National Park in western Uganda (0°33'S, 30°21'E), I observed the fishing spider *Thalassius spinosissimus* (or possibly *T. margaritatus*) (Pisauridae) consume air-breathing *H. albolabris* tadpoles at two different sites. In each case, the spider seized a tadpole as it surfaced to breathe. After struggling to subdue the tadpole as it swam downward, the spider resurfaced and carried the tadpole to the shoreline or a nearby perch above the water, where it was consumed without evidence of toxicity. *Hylarana albolabris* tadpoles can reach 3.8 g wet mass and 74 mm TL. Both spiders captured tadpoles of approximately the same length as their leg span (ca. 50 mm) and of a much greater mass.

Thalassius fishing spiders are among the most common invertebrate predators found at many forest pools and streams in Kibale National Park. *Hylarana albolabris* may be particularly susceptible to fishing spiders because they must breath air regularly, and thus are often exposed to surface predators. Although breeding in chronically hypoxic waters may reduce the diversity or efficiency of predators to which *H. albolabris* are exposed (McIntyre and McCollum, in prep.), it increases their susceptibility to certain predators, such as fishing spiders, which attack air breathers. This may explain why *H. albolabris* does not rest near the surface or use aquatic surface respiration (Kramer and Mehegan 1981. Envir. Biol. Fish 6:299–313), as observed in some North American tadpoles. The importance of fishing spiders as predators on air-breathing tadpoles should be explored elsewhere, particularly in the tropics.

PTYCHADENA MASCARENIENSIS MASCARENIENSIS (NCN). **DIET**. During February 1999, we observed an adult *Ptychadena m. mascareniensis* (Ranidae) consuming other frogs at two sites in southeastern Madagascar. On 5 February, in a rice paddy near the village of Amboavola (25°4'S, 46°46'E) a large (ca. 50 mm SUL) *P. m. mascareniensis* was observed beginning to swallow a smaller live conspecific (ca. 30 mm SUL). Processing of the prey required ca. three minutes as it was slowly engulfed head-first. The second observation was made in a bog at the Mandena littoral forest (25°58'S, 47°00'E) on 16 February. A 49 mm SUL *P. m. mascareniensis* was seen lingering for more than 30 minutes near a small (70 cm diam) temporary pool where more than ten male *Mantidactylus wittei* were calling. It seized one of the *M. wittei* (18 mm SUL) by a rear leg, and began attempting to swallow it. The prey struggled intensely for the first two minutes, them moved little in the following three minutes as it was swallowed. It was consumed posterior first, as the *P. mascariensis* employed a slightly inertial feeding strategy, especially early in the process, when it opened its mouth quickly, then rapidly made a small anterior movement of its body. In the *P. m. mascareniensis'* stomach, one rear limb of the *M. wittei* was in the normal resting position while the other was extended forward to the head. We did not observe the initial seizure of the prey, so cannot comment on the use of the tongue. When it had completely swallowed the prey, we captured and preserved the *Ptychadena* for dissection. In addition to the *M. wittei*, the stomach contained a snail (6 mm diam), a small grasshopper (5 mm), a beetle grub (6 mm), and two types of vegetation. The vegetation may have been secondarily ingested along with the frog.

This is the first record of carnivory by *P. m. mascareniensis*, which is widely distributed across all of Madagascar. In most disturbed areas, it is the largest and most abundant frog, and can be found active during day and night. Thus, if carnivory is a regular habit of *P. m. mascareniensis*, it may be an important predator on syntopic small frogs such as *Heterixalus* and *Mantidactylus*. We also note that inertial feeding is atypical of anurans and merits further investigation.

RANA CATESBEIANA (Bullfrog) **RECORD SIZE.** A record size *Rana catesbeiana* from Oklahoma, measuring 20.4 cm SVL, was reported by Lutterschmidt et al. (1996. Herpetol. Rev. 27:74–75). Here we report a larger female, 22.0 cm from the tip of the snout to the posterior edge of the vent, in the collection of the Museum of Comparative Zoology, Harvard University. The specimen (MCZ-A-25600) was collected June 1942 (collector unknown) from the north shore of Lake Verret, Atchafalya Basin, Assumption Parish, Louisiana, USA.

We thank James D. Lazell, Jr. for the measurement, and José P. Rosado for confirmation of the measurement and for use of the MCZ collection.

SCYTHROPHRYS SAWAYAE (NCN). **DEFENSIVE BEHAVIOR**. Stiff-legged defensive behavior that involves limb immobility and distention was described by Sazima (1978. Biotropica 10[2]:158) for the anurans *Proceratophrys appendiculata* (Leptodactylidae) and *Stereocyclops parkery* (Microhylidae), leaf litter inhabitants of the Atlantic Rainforest of southeastern Brazil. This behavior is also known for *Zachaenus parvulus* (Leptodactylidae) (Sazima, *op. cit.*) and *Proceratophrys boiei* (Leptodactylidae) (Pombal Jr., pers. com.). During studies at Rancho Queimado (27°30'S 49°00'W, 800 m), Serra Geral in Santa Catarina State, Brazil, this behavior was also observed in the leptodactylid frog, *Scythrophrys sawayae*, an inhabitant of the leaf litter in the Atlantic Rainforest of Paraná and Santa Catarina in southern Brazil. Nineteen *S. sawayae* were collected from 1991 to 1995 and were maintained in captivity for 3–5 days. While handling the frogs, I observed that, after being disturbed, individuals would leap 10–20 cm and fall immediately with their vent down, their body fixed to the ground, and their limbs outstretched and rigid (Fig. 1). They remained stationary in this posture for between 30 sec and 10 min. All individuals, independent of sex, including amplexed pairs, demonstrated this behavior while in captivity (Fig. 2). During December 1997 this behavior was observed in the field in individuals engaged in reproductive activity. Some individuals fled from capture by jumping into shallow ponds (± 20 cm deep) where they remained stiff-legged, even while submerged.

Sazima (*op. cit.*) suggested that this defensive behavior would be associated with the cryptic coloring of the dorsum (similar to dead leaves), although *S. sawayae* shows a different coloration. The specimens present three patterns of dorsal coloring: dark brown (50%, N = 16), green (28%, N = 9), and light brown (22%, N = 7). The dorsal surface of the limbs is yellowish brown, diverging from the dorsal coloring of the body. Dorso-lateral ridges are defined by a fine white line, and extend from the posterior region of the eyelids to the inguinal region. Below these, there is a lateral black strip. While the individual is immobile, the dorso-lateral ridges are more pronounced, and in conjunction with the color difference between the dorsum and the limbs this creates a disruptive effect, breaking the image of the animal from a distance. The chromatic polymorphism also camouflages the individual as it occupies a heterogeneous environment on the forest ground (Edmunds 1974. Defense in Animals. Longman, Harlow. 357 pp.; Krebs and Davies 1978. Behavioural Ecology. Blackwell, London. 494 pp). These chromatic characteristics achieve the same cryptic effect as the "dead leaf" coloration (Sazima, *op. cit.*) and, with the stiff-legged behavior, act by impeding the formation of search images by visually oriented predators that disturb the litter in search of food.

Observation of this behavior in *S. sawayae* reinforces the observation of Sazima (*op. cit.*) that there is behavioral convergence among anuran species that inhabit leaf litter and are subject to the same type of predation pressure.

Voucher specimens include: Coleção Célio Fernando Baptista Haddad (CFBH 2976–2978), deposited in Universidade Estadual Paulista, Departamento de Zoologia, Rio Claro, SP, Brazil; Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul (MCP 2064–75), Porto Alegre, RS, Brazil.

I thank Christine Strussmann and Célio F. B. Haddad for reviewing this note and CAPES for the fellowship.

TESTUDINES

CHELONIA MYDAS (Green Sea Turtle). **NESTING DISTRIBUTION.** The waters off the North Carolina (USA) coast have been historically viewed as feeding grounds for the green sea turtle, *Chelonia mydas* (Hirth 1971. FAO Fish. Synop. 85). North Carolina beaches have not been considered nesting grounds for this species (Meylan et al. 1995. Florida Mar. Res. Publ. 52:1–51), although Schwartz et al. (1981. ASB Bull. 28:96) reported one tagged individual that nested five times in North Carolina during the summer of 1980. Here, we demonstrate that the green sea turtle regularly nests on North Carolina beaches.

From 1980 to 1994, 34 green sea turtle nests were recorded on North Carolina beaches. Nests were reported from 10 different beaches with the highest concentrations occurring at Camp Lejuene Marine Base (N = 17), Bald Head Island (N = 7), and Cape Hatteras National Seashore (N = 3). The remaining seven beaches had one nest each. The number of nests per year varied from zero to nine and averaged (± standard error) 2.27 ± 0.73 nests. We know that more than one turtle is responsible for these nests due to multiple tag returns in 1992 and 1994. For 32 nests, the average number of eggs per nest was 165 ± 4.27. Four tagged individuals laid an average of 3.40 ± 0.68 nests per season with 11 nesting intervals averaging 12.64 ± 1.60 days. The average hatch rate was 77.84 ± 4.68% for 32 nests and the average incubation was 62.48 ± 1.16 days for 25 nests. Hatch rate was significantly (one-way ANOVA, df = 2, 29, P = 0.003) greater for nests laid in June (90.73 ± 1.99%) and July (82.38 ± 6.97%) than for those laid in August (52.75 ± 10.83%).

Historically, Amelia Island, Florida, was thought to be the northern boundary for green sea turtle nesting (Dodd 1982. Brimleyana 7:39–54). However, due to the regular nesting for the past 15 years on North Carolina beaches by the green sea turtle, North Carolina should be considered the northernmost limit of the nesting range of this species.

CHRYSEMYS PICTA MARGINATA (Midland Painted Turtle). **RETICULATE MELANISM**. Reticulate melanism (RM) in painted turtles refers to a netlike or vermiculate pattern of black markings on the carapace, found in addition to any normal carapacial patterns. The pattern was first reported by Smith et al. (1969. J. Herpetol. 3:173–176) as occurring occasionally in adult male western painted turtles (*Chrysemys picta bellii*) from North Dakota. Ernst and Ernst (1972. J. Minnesota Acad. Sci. 38:77–80) found RM in six male and three female *C. p. bellii* from Lake Shetuck in Minnesota, MacCulloch (1981. J. Herpetol. 15:181–185) noted the pattern in Canadian *C. p. bellii*, and Schueler (1983. Blue Jay 41:83–91) added that Canadian *C. p. bellii* with carapacial RM also typically have the dorsal head stripes interrupted by a reticulate or vermiculate pattern. Stuart (1998. Herpetol. Rev. 29:80–82) found RM to be common in, and restricted to, male *C. p. bellii* from New Mexico, with a developmental sequence of cephalic RM appearing initially, followed by a progressive anterior-to-posterior spread of carapacial RM.

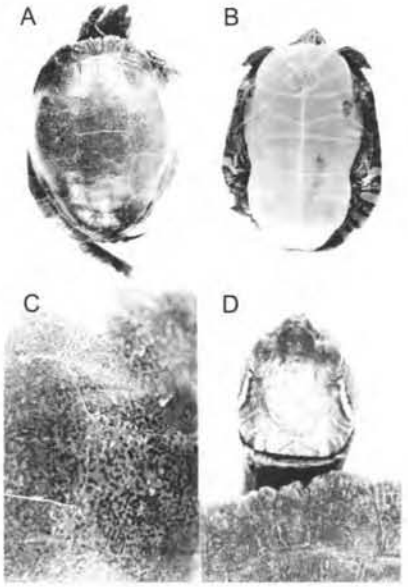

FIG. 1. A female midland painted turtle (*Chrysemys picta marginata*) collected in Shiawassee County, Michigan, in July, 1998. A. dorsal view, showing vermiculate patterning on entire carapace; B. ventral view, showing lack of typical plastral patterning of *C. p. marginata*; C. close-up of upper right quadrant of carapace, showing details of melanistic patterning; D. dorsal aspect of head, showing lack of reticulate or vermiculate pattern.

All reports of RM have been for *C. p. bellii*, and all except that of Ernst and Ernst (*op. cit.*), have found it only on adult males. Here I report a pattern resembling RM in a female *Chrysemys picta marginata* (14.1 cm straight-line carapace length, Fig. 1A). The animal (deposited at the Florida Museum of Natural History, UF 116102) was the only one of 86 turtles collected in 1998 in Shiawassee and Clinton Counties, Michigan (USA), to display this pattern. It had a typical *C. p. marginata* degree of disalignment of carapacial scutes (90.1%, using the method of Hartman 1958. Copeia 1958:261–265), but lacked the usual plastral patterning (Fig. 1B); however, the lack of a plastral pattern is not unusual in *C. p. marginata*: seven others in this sample also lacked a plastral pattern. The RM occurred on the entire carapace (Fig. 1A), and is perhaps more aptly termed vermiculate than reticulate (Fig. 1C). There was no clear evidence of cephalic RM (Fig. 1D).

This is apparently the first report of RM in a subspecies of *Chrysemys picta* other than *bellii*, and the only one other than that of Ernst and Ernst (*op. cit.*) for a female. In a study in progress, we have seen RM in other *C. p. bellii*, but we have not seen it in *Chrysemys picta picta* (29 from Massachusetts, 12 from Rhode Island, 107 from Connecticut, 28 from Virginia, 21 from North Carolina, 29 from South Carolina, 44 from Georgia), *C. p. dorsalis* (15 from Mississippi, 38 from Louisiana, 5 from Arkansas), or other *C. p. marginata* (24 from Michigan, 9 from Ohio, 4 from Tennessee).

I thank M. Nie for aiding in the collection of turtles in Michigan, and H. Smith-Somerville for taking and preparing the photographs. This investigation was partly supported by grant #IBN-9603934 from the National Science Foundation.

Submitted by **GORDON R. ULTSCH**, Department of Biological Sciences, University of Alabama, Tuscaloosa, Alabama 35487, USA (e-mail: Gultsch@biology.as.ua.edu).

CLEMMYS INSCULPTA (Wood Turtle) and ***EMYDOIDEA BLANDINGII*** (Blanding's Turtle). **HYBRIDIZATION.** Intergeneric hybridization in turtles is apparently uncommon; most reported instances have occurred under captive conditions (Fritz 1995. Herpetofauna 17:19–34). Here we report repeated occurrences of hybridization between the emydine turtles *Clemmys insculpta* and *Emydoidea blandingii* in a semi-natural enclosure.

In August 1997 a clutch of 12 hatchling turtles was discovered during the examination of a prepared sand nesting mound within a 0.1 ha research enclosure in Ingham County, Michigan, USA. The enclosure includes a 670 m^2 pond with an average depth of about 1 meter. A variable number of freshwater turtles are maintained within this enclosure; these include research specimens as well as several donated specimens of pet trade or unknown origin, used for educational purposes. In spring of 1997 this population included four mature *Clemmys insculpta* (one male and three females) and two mature *Emydoidea blandingii* (one male and one female), as well as various deirochelines (*Chrysemys, Pseudemys, Graptemys*) and several *Sternotherus odoratus*. The male *Clemmys insculpta* had previously lost two limbs and had suffered severe damage to its cloaca and penis in a raccoon attack; it was assumed to be incapable of reproduction.

The hatchling turtles were recognized to be anomalous based on coloration and details of morphology; a hybridization event was suspected but could not be confirmed based on external morphology. Tissues of one hatchling (killed accidentally during nest excavation) were subjected to DNA analysis (by SKD at Texas A&M University). Comparison of mitochondrial DNA confirmed that the mother of the hatchlings had been *Clemmys insculpta*. Paternity was resolved by using the microsatellite method (Weber and Wong 1993. Hum. Mol. Gen. 2:1123–1128); this confirmed that the clutch had been fathered by an *Emydoidea blandingii*.

In June 1998 one of the captive female *C. insculpta* deposited a clutch of 12 eggs in the enclosure. Hatchlings resulting from this nesting were also obvious hybrids. It is presently unknown whether the 1997 and 1998 clutches shared the same mother. The presumed father (*Emydoidea blandingii*) of the 1997 clutch had been released in June 1997, and a second male *E. blandingii* had been present for

about three weeks in May 1998. Thus, the 1998 hatchlings were either fathered by a different *E. blandingii* than the 1997 hatchlings, or were the result of long-term sperm storage in the female *C. insculpta*, a phenomenon presently unreported for this species, but known in *Emydoidea* (unpublished data).

The hybrid turtles display coloration and morphology that can be interpreted as intermediate between parental species, as well as features that may be unique: the hatchling carapace is light tan to dark brown, mottled with black pigment, and is keeled, broad but slightly elongate, with posterior marginal serrations; the lateral sutures of the first vertebral scute are nearly aligned with the lateral sutures of the first anterior marginal scutes; the terminus of the upper jaw is weakly notched, without cusps; the head is black or brown above, prominently marked with lateral and descending tan or yellow stripes and blotches; there is a large light spot or blotch on each side of the neck; the throat is pale yellow, invaded by dark striping. With growth, the carapace tends to elongate and darken, while becoming heavily flecked with yellow; the chin and throat become mostly yellow; and the soft skin on the neck and under the legs becomes a darker yellow-orange. The post-hatchling plastral pattern is yellow with black lateral blotches, a trait shared by both parental species. Hybrid specimens are being captive-raised to investigate questions about adult coloration and morphology, possible plastral hinge development, fertility, sex determination, and behavior.

We speculate that hybridization between *Clemmys insculpta* and *Emydoidea blandingii* could occur under natural conditions, as they are sympatric over portions of the Upper Great Lakes region. While *C. insculpta* prefers lotic habitats, as opposed to the lentic tendencies of *Emydoidea*, one of us (JHH) has frequently noted each species in habitat more typical of the other.

Submitted by **JAMES H. HARDING**, Michigan State University Museum, East Lansing, Michigan 48824, USA (e-mail: hardingj@pilot.msu.edu), and **SCOTT K. DAVIS**, Department of Animal Science, Texas A&M University, College Station, Texas 77843, USA.

PHRYNOPS WILLIAMSI (Williams' Side-necked Turtle). **PREDATION**. The mayuato, *Procyon cancrivorus*, is a nocturnal mammal (Carnivora: Procyonidae) that feeds mainly on crabs, fish, insects, molluscs, amphibians, and occasionally on fruits (Bisbal 1986. Mammalia 50:329–339; Emmons 1990. Neotropical Rainforest Mammals. Univ. of Chicago Press, Chicago, Illinois. 281 pp.). Individual mayuatos eat in specific places called rompederos, which are normally located on the banks of rivers and streams, and are so characteristic that they can be used to confirm the presence of this species in an area. On 9 June 1993, one of us (SB), travelling along a river at Iguazú National Park (25°39'S, 54°20'W) in Misiones Province, Argentina, found crabs and portions of the shell of a juvenile turtle (est. one year of age), identified as *Phrynops williamsi*, in the rompedero of a mayuato. As far as we know, this is the first account of mayuatos feeding on turtles. The reference material is housed at the Herpetological Collection, Fundación Miguel Lillo (FML 07764). The identification of the turtle was verified by Gustavo Scrocchi (FML).

TRACHEMYS GAIGEAE (Big Bend Slider). **ENDOPARASITES**. In the only study of parasites of *Trachemys gaigeae*, McAllister et al. (1995. J. Parasitol. 81:804–805) reported seven species of *Eimeria* (Apicomplexa: Eimeriidae) from turtles collected at Bosque del Apache National Wildlife Refuge, Socorro Co., New Mexico, USA (33°48'N, 106°53'W). Herein we report two species of helminths from a *T. gaigeae* taken in the same study area.

On 1 August 1996, a previously-marked *T. gaigeae* (immature female; 182 mm maximal straight-line carapace length, SCL; 790 g) was found drowned in a hoop trap in a pond that was ca. 1 m deep. The specimen was frozen and later dissected, at which time the stomach, intestines, kidneys, and lungs were removed and examined for helminths. The contents of the gastrointestinal tract (mostly filamentous algae, with fragments of aquatic insects, crayfish, and aquatic vascular plants) were also examined. Helminths were found only in the small intestine and included the digenetic trematode *Telorchis corti* (N = 11) and the spirurid nematode *Serpinema trispinosum* (N = 2 females). Trematodes were fixed in 10% buffered formalin, stained with Semichon's aceto-carmine, dehydrated in an alcohol series, mounted in Canada balsam, and identified using characteristics in MacDonald and Brooks (1989. Can. J. Zool. 67:2301–2320). Nematodes were cleared with lactophenol and identified using characteristics in Baker (1979. Can. J. Zool. 57:934–939) and Moravec and Vargas-Vázquez (1998. J. Nat. Hist. 32:455–468). Voucher specimens are deposited in the U.S. National Parasite Collection (Animal Parasitology Institute, Beltsville, Maryland, USA) as USNPC 88139 (*T. corti*) and 88140 (*S. trispinosum*). Both helminths are the first records for *T. gaigeae* and for New Mexico.

The *T. gaigeae* (University of New Mexico Museum of Southwestern Biology, MSB 60413) was first captured and released in a pond ca. 200 m from her drowning site on 19 July 1994 when she was 122 mm SCL and 228 g. A fecal sample obtained at that capture included six species of *Eimeria* (McAllister et al. 1995, *op. cit.*).

Telorchis corti parasitizes many turtle species, including emydids (Ernst and Ernst 1977. Bull. Maryland Herpetol. Soc. 13:1–75); metacercariae occur in aquatic snails, fingernail clams, and amphibian larvae. *Serpinema trispinosum* parasitizes Nearctic turtles (Baker 1979, *op. cit.*); paratenic hosts include lymnaeid snails and fish (Bartlett and Anderson 1985. J. Invert. Pathol. 46:153–159; Moravec et al. 1998. J. Parasitol. 84:454–456). *Trachemys gaigeae* is an omnivore and scavenger (JNS, pers. obs.), and probably consumes various potential intermediate and paratenic hosts for these helminths.

We thank J. Taylor, M. Oldham, and P. Norton (U.S. Fish and Wildlife Service) for facilitating work at the refuge under Special Use Permit No. 73599 (to JNS), and two anonymous reviewers for comments. Work by JNS was funded by the New Mexico Department of Game and Fish Share With Wildlife Program.

LACERTILIA

COLEONYX VARIEGATUS (Western Banded Gecko). **DIET.** *Coleonyx variegatus* is not known to consume centipedes (Pianka 1986. Ecology and Natural History of Desert Lizards. Princeton University Press, Princeton, New Jersey. 208 pp.), nor have they been reported to consume carrion. Parker and Pianka (1974. Copeia 1974:528–531) reported the stomach contents of 185 *C. variegatus*, none of which contained centipede remains. On 16 May 1998 at 2015 h in Pima County, Arizona (USA), one of us (JRM) discovered an adult male *C. variegatus* (SVL 64 mm) attempting to consume a road-killed *Scolopendra* sp. much larger than itself (TL 82 mm; Fig. 1). The temperature was 21°C.

The centipede was adhered to the road by dried entrails and the gecko was observed struggling to engulf it for approximately 5 minutes. After this time we took a photograph and the camera flash appeared to cause the gecko to regurgitate the centipede and attempt to escape; our measurements indicate that ca. 30 mm of the centipede had been ingested. Because of the size of the centipede, it seems unlikely that this gecko was capable of consuming this prey item whole. The fact that this centipede was apparently dead before the gecko attempted ingestion appears significant because large *Scolopendra* spp. have been reported to prey upon small lizards (Lewis 1981. The Biology of Centipedes. Cambridge University Press, Cambridge. 476 pp.).

Both the *C. variegatus* and the *Scolopendra* sp. are deposited in the University of Texas at Arlington, Collection of Vertebrates (UTA R-45195).

CROTAPHYTUS COLLARIS (Eastern Collared Lizard). **HIBERNACULUM.** Temperate lizards often survive freezing winter temperatures by digging burrows in which they hibernate (Gregory 1982. *In* C. Gans and H. Pough [eds.], Biology of the Reptilia Vol. 13, pp. 53–154. Academic Press, New York). *Crotaphytus collaris* has been previously reported to dig hibernacula on sloping terrain beneath flat rocks that are partially embedded in soil (Legler and Fitch 1957. Copeia 1957:305–307). On 24 March 1998, I observed a collared lizard emerging from a subterranean burrow on nearly flat open grassland, not beneath surface rocks. The burrow was almost certainly used as a winter hibernaculum because this was the first of five survey dates that lizards were active, and because the integument of this lizard was covered with caked mud. The observation was made at the flood control spillway at the Arcadia Lake Dam (AL) located 9.6 km east of Edmond, Oklahoma (USA), on State Hwy 66. Capture and examination of the animal revealed that it was a male (84 mm SVL) that had been toe-clipped as a hatchling on 3 August 1997, and was beginning its first full season of activity in 1998. The burrow was dug in clay soil interspersed with small (1–4 cm) rocks, 1 m from the edge of a patch of larger boulders inhabited by collared lizards at AL, and 22.2 m (minimum linear distance) from the home range occupied by this lizard as a hatchling. To study burrow architecture, I made an internal cast by pouring marine resin down the entrance (Chapman et al. 1990. J. Kansas Ent. Soc. 63:641–643). The burrow cast revealed a round entrance 4.5 cm in diameter that led into the burrow neck (8–9 cm diameter), which penetrated the substrate at a 80° angle relative to the surface horizontal (Fig. 1). At a depth of 11 cm, the shaft turned in a J-shape to form a blind-ended chamber (20 cm long and 9–11 cm in diameter). Unlike the chambers described by Legler and Fitch (*op. cit.*), this chamber was more than large enough to accomodate the lizard that I saw emerging from it. The bottom of the chamber was loose sand located 21 cm below the surface, which is 3.5 cm deeper than the average frost penetration of 17.5 cm in central Oklahoma (Anonymous 1938. Heating and Ventilating 35[6]:84).

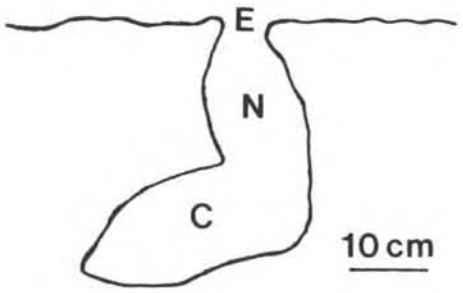

FIG. 1. *Crotaphytus collaris* hibernaculum showing the entrance (E), burrow neck (N), and chamber (C).

SERPENTES

HETERODON NASICUS NASICUS (Plains Hognose Snake). **LACK OF PARALYSIS FOLLOWING VERTEBRAL DISJUNCTION.** On 30 September 1997 at 1008 h, a male *Heterodon nasicus nasicus* (57.0 cm SVL) was found on County Rd B.5 at the junction of County Rd 12, Two Buttes State Wildlife Area, Prowers County, Colorado, USA. The snake has three scars on its dorsum; the most posterior caused constriction of the tail, the middle scar was a large patch with missing scales and the most anterior had bone protruding through the skin but no missing scales. At the point at which the bone protruded (26 cm from snout), the vertebral column was obviously misaligned. Radiographs of the snake showed near complete disjunction of the vertebral column at the region where the bone protrudes through the skin, an area of calcification associated with the large patch of missing scales and constriction of the tail but no internal injury associated with the posterior scar. The vertebral column is upturned anterior to a 0.75 mm separation at the anterior scar, and one vertebra is disarticulated and damaged, and protrudes through the skin (Fig. 1); however, limited muscle control indicates the spinal column is at least partially intact. The snake has fed on young mice since its capture and normal defecation has followed. The snake has limited voluntary muscle control posterior to the vertebral misalignment, although some localized areas appear not to respond to stimulus. The snake compensates for the posterior portion of the body with the anterior portion, which has resulted in some hypertrophy of the anterior and slight atrophy of the posterior musculature of the body. The extensive healing of

the scarred regions, and the level of muscle hypertrophy/atrophy suggests that this snake had survived in the wild for some time (>1 year) after being injured.

Smith and Fitzgerald (Herpetol. Rev. 1983. 14:46) reported the first trauma-induced kyphosis in a snake, *Thamnophis radix haydeni*. This specimen had normal motor function and was eating well, although gross vertebral deviations were apparent in radiographs. Complete paralysis posterior to a vertebral column break has been noted previously in a female *Thamnophis elegans vagrans* (Kasper 1997. Herpetol. Rev. 28:46). This snake was feeding normally and gave birth to three low-birth-weight young, which subsequently died. The fact that these garter snakes and the hognose snake were alive and functioning close to normally, in spite of a broken vertebral column, is indicative of the resiliency of snakes in general.

The hognose snake is currently housed in the Animal Facility of the University of Northern Colorado and will be deposited in the UNC Museum of Natural History Herpetology collection upon its death. A scientific collecting permit (97-0456) was issued to Stephen P. Mackessy by the Colorado Division of Wildlife (CDOW). We thank CDOW and the Great Outdoors Colorado Program for funding the project under which this specimen was collected. We thank Roger Klingenberg for assistance with interpreting radiographs.

Submitted by **CHAD MONTGOMERY** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, 501 20th St., Greeley, Colorado 80639, USA (e-mail [SPM]: spmacke@bentley.unco.edu).

LAMPROPELTIS GETULA NIGRA (Black Kingsnake). **ENDOPARASITES**. Although internal parasites have been reported in *Lampropeltis getula* and a congener (Lindsay et al. 1992. J. Helminth. Soc. Washington 59:9–15; Klingenberg 1993. Understanding Reptile Parasites. Advanced Vivarium Systems, Lakeside, California. 81 pp.), specific endoparasites have yet to be described. I identified internal parasites and calculated their relative prevalence and intensity (Goldberg and Bursey 1996. Herpetol. Rev. 27:19) in the cloacal discharges (primarily feces) of naturally infected *L. g. nigra*.

Snakes were captured from the Anderson County Wildlife Sanctuary (ca. 36°03'N, 84°10'W) located in Anderson County, Tennessee, USA. Metal and wood cover objects (N = 150) were scattered over a 10-ha area (environments included recovering landfill, old field habitat, and woodland-field ecotone), and were searched for ca. 4 h/wk between 1 April and 1 October, 1994–1997. Cloacal discharges were collected from captured *L. g. nigra* by gently massaging the ventral side sequentially from anterior to posterior, down to the cloaca. Samples were stored in 10% formalin, and upon examination were treated with sodium nitrate as described in Kelly (1977. Canine Parasitology. Univ. Sydney Post-Graduate Foundation in Veterinary Science, Sydney, Australia. 110 pp.). Suspensions of discharges were examined using a compound microscope, and parasite ova and larvae were identified as described in Barnard (1986. Compendium on Continuing Education 8:145–369), and Barnard and Upton (1994. A Veterinary Guide to the Parasites of Reptiles. Krieger Publ. Co., Malabar, Florida. 164 pp.).

Twenty-two cloacal discharges were collected from 22 different snakes (13 M, 9 F; mean ± SD [range] SVL = 67.0 ± 21.0 cm [31.5 ± 106.0 cm]). Prevalence (number of infected individuals/number individuals examined) and mean intensity (mean number parasites per infected host) were recorded for each parasite (Table 1). Infection by both species of nematodes was observed in 3 (13.6%) samples. While nematodes were the most prevalent parasites, cestodes (tapeworms) were observed in zero (0%) samples. This observation is consistent with past research, which has demonstrated that wild reptiles are primarily infected by nematodes and generally not infected by cestodes (Frank 1994. Endoparasites. *In* Cooper and Jackson (eds.), Diseases of the Reptilia, pp. 291–321. Academic Press, New York, New York). Voucher parasite specimens will be deposited in the U.S. National Parasite Collection (USNPC), Beltsville, Maryland.

I especially thank John G. Byrd for the opportunity to conduct this study, and John E. Fauth for helpful suggestions concerning the manuscript. This study was funded by DOE grant DE-FG05-930R22105.

TABLE 1. Prevalence and mean intensity of endoparasites in cloacal discharges of *Lampropeltis getula nigra* (N = 22).

Parasite	Prevalence (%)	Intensity (Mean ± SD)
Nematoda		
Strongyloides spp.	45	2.8 ± 2.4
Ascaris spp.	14	1.3 ± 0.5
Trematoda		
Ochetosoma spp.	18	1.3 ± 0.5
Coccidia		
Eimeria spp.	18	24 ± 15

Submitted by **STRANT T. COLWELL, JR.**, Department of Chemistry, University of Virginia, Charlottesville, Virginia 22903, USA.

MICRURUS FULVIUS TENER (Texas Coral Snake). **DIET**. *Micrurus fulvius* is reported to feed primarily on small snakes and slender lizards (Conant and Collins 1998. Reptiles and Amphibians of Eastern/Central North America. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). Greene (1984. Spec. Publ. Univ. Kansas Mus. Nat. Hist. 10:147–162) reports that throughout its range *Micrurus fulvius* feeds almost entirely on elongated lizards, amphisbaenians, and small snakes including young *Elaphe obsoleta*. Here we report predation on *E. obsoleta lindheimeri* by *M. fulvius tener* in Texas.

On 9 September 1998, at 0800 h, an adult male *M. fulvius tener* was captured crossing a park road in Cedar Hill State Park, Dallas Co., Texas, USA. The snake (56.3 cm total length, 138.0 g) was placed in a five-gallon bucket for ca. six hours. During that time it regurgitated a juvenile *E. obsoleta lindheimeri* (ca. 24.0 cm total

length), which was partially digested and missing the anterior third of its body. The remains of the *E. obsoleta lindheimeri* were preserved and placed in the University of Texas at Arlington Collection of Vertebrates (UTA R-45192). The *M. fulvius tener* was released.

We thank Ardell Mitchell for reviewing this manuscript, and the staff of the Dallas Zoo Department of Herpetology for their support. We also thank the Texas Parks and Wildlife Department (Permit # 51-98), and the staff of Cedar Hill State Park.

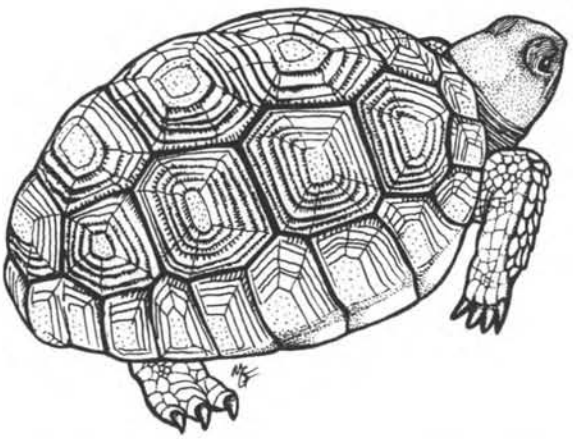
Submitted by **RICHARD D. REAMS** and **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, Dallas, Texas 75203, USA, and **JOHN M. DAVIS**, Texas Parks and Wildlife, P.O. Box 941 Cedar Hill, Texas 75106, USA (e-mail: Hylareams@aol.com).

PSEUDOBOA NIGRA (NCN). **PREY**. The limited available data on the diet of *Pseudoboa nigra* (Colubridae) suggest that it feeds primarily on lizards (Cunha and Nascimento 1983. Bol. Mus. Paraense Emílo Goeldi, Ser. Zool. 122:1–42; Vitt and Vangilder 1983. Amphibia-Reptilia 4:273–296; Strussman 1992. M.S. thesis. Universidade Estadual de Campinas, São Paulo, Brasil. 135 pp.).

On 4 May 1997 at 2230 h, while traveling on a dirt road from Barra do Cahy village to Cumuruxatiba village (17°37'S, 39°33'W) in Prado municipality, southern Bahia State, northeastern Brazil, we found a subadult female *P. nigra* (Museu Nacional do Rio de Janeiro, MNRJ 6670) preying on an adult male *Tropidurus torquatus* on the ground at the edge of roadside vegetation. The observation occurred in restinga habitat of the Atlantic Rainforest Domain. The snake (161.5 cm SVL, 18 cm tail length, 91.0 g preserved mass) was ingesting the lizard (86.7 mm SVL, 12.6 g preserved mass) head first, and the lizard's head and neck were completely ingested. Upon our arrival, the snake regurgitated and released the lizard and attempted to escape. The lizard moved ca. 2 m and stopped, remaining motionless for several minutes. Both specimens were collected and placed in the same plastic bag. The following morning, the lizard was completely ingested by the snake. This observation reinforces previous reports that *P. nigra* consumes lizards and indicates that this nocturnal snake preys on the diurnal *T. torquatus*.

The authors benefited from research grants (300 819/94-3 to CFDR, 301 372/95-0 to HGB and 300 124/96-1 to LG) from Conselho Nacional do Desenvolvimento Científico e Tecnológico ñ CNPq. We thank Ronaldo Fernandes, Curator, Herpetology Section, Museu Nacional do Rio de Janeiro, who verified the snake's identity.

PEREIRA**, Departamento de Biologia Animal e Vegetal, Instituto de Biologia Roberto Alcântara Gomes, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier, 524 Maracanã, Rio de Janeiro, RJ, Brazil (e-mail [CFDR]: cfdrocha@uerj.br).



THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). **CARRION FEEDING**. On 15 May 1998 we observed a DOR (dead on the road) *Thamnophis sirtalis sirtalis* on State Hwy 23, 2.6 km south of the intersection with County Hwy ZZ (USA: Wisconsin: Iowa Co: T6N, R3E, Sec 4). The snake (55 cm SVL) was lying next to an unidentified DOR adult passerine bird. Although both specimens were badly crushed, it was clear that the garter snake was in the process of swallowing the dead bird when it, too, was run over (Fig. 1). Owing to the badly crushed condition of the specimens, neither was retained.

The diet of *T. sirtalis* includes "young birds" (Wright and Wright 1957. Handbook of Snakes of the United States and Canada. Vol. 2. Comstock Publ. Assoc., Ithaca, New York. 1105 pp.). Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.) describe the diet of the genus *Thamnophis* as ". . . birds, and carrion, are eaten occasionally." We believe this to be the first record of *T. s. sirtalis* feeding on bird carrion.

FIG. 1. DOR *Thamnophis sirtalis*, killed while ingesting a DOR passerine bird.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 30, Number 1 (March 1999).

CAUDATA

EURYCEA TYNERENSIS (Oklahoma Salamander). USA: OKLAHOMA: LeFlore Co: Cucumber Creek, ca. 1.2 km upstream from where US Rt. 259 intersects Cucumber Creek (34°36'26"N, 94°36'54"W), Sec. 8, T1N, R25E, Octavia quadrangle. 20 May 1999. Sam Houston State Vertebrate Museum (SHSVM 1-99 and 2-99). Verified by R. D. Durtsche. New county record; extends geographic range ca. 96.5 km S of Sequoyah County into the most south-central part of LeFLore County. Cucumber Creek is an intermittent stream with small isolated pools along the creek bed. Pool substrates consists of large boulders to small limestone cobbles with some organic detritus. At the time of specimen collection, the creek had moderate flow with only a few isolated pools observed within higher levels of the creek bed.

EUPSOPHUS EMILIOPUGINI. ARGENTINA: CHUBUT: Cushamen Department: Lago Puelo National Park, Arroyo Melo (42°07'50"S, 71°43'18"W), 415 m elev. 12 March 1998. C. A. Úbeda. Museo Argentino de Ciencias Naturales "Bernardino Rivadavia" MACN 36786. Verified by J. R. Formas. First record for Argentina. Two mature females were found in a forest that represents the only ingression of the Chilean valdivian rain forest at low altitude toward the east through the Andes. Species is distributed in Chile from Puyehue (40°42'S, 72°18'W) to Caleta Vidal (45°16'S, 73°27'W) (Formas 1989, Proc. Biol. Soc. Washington 102[3]:568–576). The nearest previously known locality was Río Lenca (41°37'S, 72°27'W) in Chile. Extends the distribution of the species 98 km SE from Río Lenca, to the E of the Andes, at the proximity of a trans-Andean pass of low altitude (200 m elev. at Río Puelo).

Submited by **CARMEN A. ÚBEDA**, Centro Regional Bariloche, Universidad Nacional del Comahue, Unidad Postal Universidad, 8400 Bariloche, Argentina (email: cubeda@bariloche.com.ar), **EDUARDO RAMILO** and **CLAUDIO CHEHÉBAR**, Administración de Parques Nacionales, Delegación Regional Patagonia, C.C. 380, 8400 Bariloche, Argentina (email: pndrp@bariloche.com.ar), and **FÉLIX VIDOZ**, Parque Nacional Lago Puelo, 8431 Puelo, Argentina.

HYLA BOANS (Giant Gladiator Treefrog). VENEZUELA: ESTADO TÁCHIRA: Valle del Río Doradas, 650 m elev. 10 November 1984. Collected by Proyecto Uribante-Caparo, Facultad de Ciencias, Universidad de los Andes. Colección de Vertebrados, Universidad de los Andes, Facultad de Ciencias (CVULA 3573). Verified by A. Orellana. Species was known in Venezuela (Barrio 1998, Acta Biol. Venezuela 18[2]:28) in three bioregions: Amazonian Venezuela, Guianan Shield, and Orinoco Delta, all related to lowland rainforests in southern and eastern Venezuela. Only known report of this species in western Venezuela; extends distribution 600 km NW of the nearest known record in the country at Tobogán de la Selva, 30 km out of Puerto Ayacucho, Amazonas (Barrio 1998, *op. cit.*; Hoogmoed 1990, Zool. Meded. 64:71–93). Presence of *Hyla boans* in the Río Doradas valley was anticipated as this zone is the only Amazonian relict in Andean Venezuela, as appears in Barrio´s map (1998, *op. cit*: 93) of the biogeographic regions in relation to amphibian distribution.

Submitted by **CÉSAR LUIS BARRIO AMORÓS**, Fundación ANDÍGENA, Apartado 210, 5101-A Mérida, Venezuela (email: clba@hotmail.com).

HYLA URUGUAYA. BRAZIL: PARANÁ: Palmas municipality (ca. 26°30'S, 52°00'W). 6 September 1998. P. S. Bernarde and A. A. Giaretta. Museu de História Natural da Universidade Estadual de Campinas, Campinas, São Paulo (ZUEC 11551). Verified by Ariovaldo A. Giaretta. Species was previously known from a few localities in Uruguay and the state of Rio Grande do Sul, Brazil (Langone 1990, Com. Zool. Mus. Hist. Nat. Montevideo 12[172]:1–9). First state record and the northernmost known locality; extends the known distribution ca. 480 km NE airline from previous records (Porto Alegre Municipality, state of Rio Grande do Sul). Individuals were found calling near ground at night in low vegetation bordering a lake.

Submitted by **PAULO SÉRGIO BERNARDE**, Curso de Pós-Graduação em Zoologia, Departamento de Zoologia, Universidade Federal do Paraná, C.P. 19020, 81531-990, Curitiba-PR, Brazil (email: bernarde@garoupa.bio.ufpr.br).

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). USA: Florida: St. Johns Co: Anastasia Island, Fort Matanzas National Monument (29°42'56.3"N, 81°13'59.0"W). 10 June 1999. K. L. Krysko and F. W. King. Florida Museum of Natural History (UF 117746). Verified by Joseph T. Collins. New county record collected at 2130 h on nature boardwalk in maritime forest. During the course of monthly surveys of amphibians and reptiles of FOMA

conducted on behalf of the U.S. National Park Service from September 1998 through September 1999, we found a total of five *Osteopilus septentrionalis,* the first as noted above. The remaining four include one specimen on 12 June 1999 at 2200 h (UF 117747), one on 10 July 1999 at 2155 h (UF 117774), and two on 10 September 1999 at 2025 h and 2115 h. A majority of the introduced amphibians and reptiles in southern Florida have been unable to expand their range north of Lake Okeechobee because of cold winter temperatures (Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9). However, some species including the Brown Anole (*Anolis sagrei*) and Greenhouse Frog (*Eleutherodactylus planirostris*) are more cold-tolerant, and edificarian species like the Indo-Pacific Gecko (*Hemidactylus garnotii*) and Mediterranean Gecko (*H. turcicus*) have found refuge from the cold in warm cracks and crevices on buildings. As a consequence, these species have established breeding populations farther north within peninsular Florida and along both coasts. Because all five *O. septentrionalis* we collected at FOMA are adults of variable sizes, this suggests that if not already, there soon may be breeding populations of this non-indigenous frog species all along the northeastern coast of peninsular Florida.

PHYLLOMEDUSA HYPOCONDRIALIS. VENEZUELA: COJEDES: municipio Rómulo Gallegos, Asentamiento La Blanca, Sector Rincón Moreno, SW San Carlos City, 09°34'18"N, 68°37'14"W, 140–150 m elev. 1996 (exact date not given). Numa Hurtado. Museo de la Estación Biológica de Rancho Grande, Maracay (EBRG 3582). Verified by R. Rivero. Previously known from states of Barinas, Bolívar and Apure (Rámos and Busto 1989–90, Mem. Soc. Cienc. Nat. La Salle 52–53[131-134]:287–308; Hoogmoed and Gorzula 1979, Zool. Med. Leiden 54[13]:183–206; La Marca 1992, Catálogo Taxonómico, Biogeográfico y Bibliográfico de las Ranas de Venezuela). First state record; extends range more than 150 km from the previous records.

Submitted by **GILSON RIVAS**, Fundación La Salle de Ciencias Naturales, EDIAGRO, Avenida Bolivar No. 20-1219, San Carlos 2201, Estado Cojede, Venezuela (email: quisyl@cantv.net) and **JESÚS MANZANILLA**, Instituto de Zoología Agrícola, Facultad de Agronomía, Universidad Central de Venezuela, Estado Aragua, Venezuela (email: jmanzanil@cantv.net).

PHYLLOMEDUSA TOMOPTERNA. VENEZUELA: AMAZONAS: Mavaca (Yanomami village), Mavaca River, upper Orinoco drainage. 28 June 1981. J. Finkers. Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (EBRG 2938). BOLÍVAR: Reserva Forestal Imataca, 180 m elev. May 1990. L. Balbás. EBRG 2455. Both verified by Gilson Rivas. Species has been reported previously in Venezuela from only two localities, one at the base of the Cerro de la Neblina (state of Amazonas) by McDiarmid and Paolillo (1988, *In* Brewer-Carías [ed.], Cerro de la Neblina, Resultados de la Expedición 1983–1987. FUDECI, Caracas), on the basis of voucher specimens apparently deposited in USNM and the other by Duellman (1997, Univ. Kansas Nat. Hist. Mus. Sci. Pap. 2:1–52) at Km 13 on the road between El Dorado and Santa Elena de Uairén, Estado Bolívar (KU 167188). We report the first vouchered specimens discovered in a Venezuelan museum; corroborates the above records and extends known distribution ca. 200 km NNE in state of Amazonas, and 100 km NNE in state of Bolivar.

Submitted by **CÉSAR LUIS BARRIO**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, 1010-A, Venezuela (email: fudeci@reacciun.ve and cesarlba@yahoo.com), and **RAMÓN RIVERO**, Museo de la Estación Biológica Rancho Grande, MARNR, Apartado 184, Maracay, Aragua, Venezuela.

PLEURODEMA NEBULOSA. ARGENTINA: RIO NEGRO: Departamento de San Antonio Oeste: Las Grutas (40°48'S, 64°44'W). 24 January 1997. R. Martori and L. Aun. Colección de Vertebrados Universidad Nacional de Río Cuarto, Córdoba, Argentina (ZVUNRC 4047). Verified by G. Scrocchi. First provincial report, mentioned as probably occurring by Cei (1980, Amphibians of Argentina. Monit. Zool. Ital. Monogr. 2[1]:609) and cited by Christie (1995, *In* Ubeda and Grigera [eds.], Recalificación del estado de conservación de la fauna silvestre Argentina. Consejo Asesor Regional Patagonico de la Fauna Silvestre), but no voucher specimen was referenced. Specimen was found chorusing at night in a temporary pond after a storm.

Submitted by **LILIANA AUN** and **RICARDO MARTORI**, Zoologia de Vertebrados, Universidad Nacional de Rio Cuarto, 5800 Rio Cuarto, Córdoba, Argentina (email: rmartori@exa.unrc.edu.ar).

RANA GRYLIO (Pig Frog). PUERTO RICO: TOA BAJA: SABANA SECA: wetland area known as Ciénaga de San Pedro, 2.9 km, Rt. 867 within the North Tract sector of the U.S. Naval Security Group Activity (18°27'04"N, 66°12'42"W). 12 November 1998. Neftalí Rios-López. Museo de Biología, Universidad de Puerto Rico-Recinto de Río Piedras. UPRRP 5752–54. Verified by Julian Lee. First record for Puerto Rico and the southeasternmost record for the species. A female (111.7 mm SVL) and a juvenile (68.6 mm SVL) were collected at 2200 h from a flooded channel, which runs parallel to a side road within the North Track area, where there is an apparently large population from which calling males were heard in March, August, and September 1995, and in October and November 1998. Females, sub-adults, and juveniles were observed while submerged, partially or up to the head, in open waters surrounded by vegetation. However, calling males were heard from within large clumps of *Typha dominguensis,* and these animals were not openly exposed while calling. This calling behavior might explain why the species was not previously reported. It is possible that chorusing individuals were confused with birds calling within vegetation clumps throughout the area. *Rana grylio* is present also in the Tortugero Lagoon Reserve and associated nearby wetlands (MANATI/VEGA BAJA, Tierras Nuevas Saliente, Rt. 686, 18°28'00"N, 66°27'48"W). A sub-adult (102.7 mm SVL, UPRRP 5761) and a juvenile (40.4 mm SVL, UPRRP 5762) were collected by Carlos Toledo and Neftalí Rios-López on 17 August 1999 at the edge of a small pool surrounded by *T. dominguensis.* The species was also found all along the Caño Tiburones (water channel which cuts an associated wetland area) at the northwesternmost part of its geographic distribution within Puerto Rico (Arecibo, Factor, Rt. 682, 18°27'47"N, 66°38'21"). A juvenile (53.6 mm SVL, UPRRP 5763) was collected (NRL) from within the channel on which males were heard calling in the water. All these data indicate that *Rana grylio* is well established in northern Puerto Rico and it is reproductively active during most of the year. The previous geographical range of this species includes southern South Carolina to extreme southern Florida and extreme southeastern Texas. It has been also introduced on Andros and New Providence islands in the Ba-

hamas (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **NEFTALÍ RIOS-LÓPEZ** and **RAFAEL L. JOGLAR**, Universidad de Puerto Rico, Recinto de Río Piedras, Departamento de Biología, Apartado 23360, San Juan, Puerto Rico 00931-3360, USA.

RANA SPHENOCEPHALA (Southern Leopard Frog). USA: ILLINOIS: WAYNE CO: Bedford Twp. (Sec. 34, T1N, R7E). Found dead in culvert at jct. County Roads 1550N and 1500E. 27 April 1999. J. W. Walk and T. Esker. Southern Illinois University voucher number H05719. Verified by S. Ballard. New county record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. His. Surv. Bull. 298 pp.).

Submitted by **DANIEL J. OLSON** and **JEFF W. WALK**, Department of Natural Resources and Environmental Sciences, University of Illinois, Urbana, Illinois 61801, USA.

RANA SYLVATICA (Wood Frog). USA: OKLAHOMA: ADAIR CO: Ozark Plateau National Wildlife Refuge, SW 1/4 Sec. 34, T15N, R26E. 8 September 1999. Richard C. Stark, Kevin C. Stubbs, and Steven L. Hensley. Sam Noble Oklahoma Museum of Natural History (OMNH 35836). Verified by Janalee P. Caldwell. First state record (Black and Sievert 1989, A Field Guide to Amphibians of Oklahoma. Publ. Oklahoma Dept. Wildlife Conserv. 80 pp.). Extends range ca. 30 km SW from nearest location in Washington County, Arkansas (Trauth 1995, Bull. Chicago Herpetol. Soc. 30[3]:46–51).

Submitted by **RICHARD C. STARK**, **KEVIN C. STUBBS**, and **STEVEN L. HENSLEY**, United States Fish and Wildlife Service, Oklahoma Ecological Services, 222 South Houston Avenue, Suite A, Tulsa, Oklahoma 74127, USA.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). USA: TENNESSEE: BLOUNT CO: Great Smoky Mountains National Park: Gum Swamp in Cade's Cove (35°35'21"N, 83°50'21"W). 12 July 1999. Kelly J. Irwin, C. Kenneth Dodd, Jr., and Marian L. Griffey. USNM 533211, adult male. Verified by Steve Gotte. A small chorus of <5 males calling from the center of the pond during an extremely heavy rainfall (134 mm total rain, 10–13 July). Collected 1130–1300 h; air temp 22°C; substrate temp 21°C; water temp 20°C; relative humidity 88%. Breeding evidently was successful inasmuch as a 20 mm juvenile was found at this location at dusk on 20 September 1999, during a light rain shower. New Park and county records (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol.Misc. Publ. 12. 94 pp.). These records extend the range of the *S. holbrookii* ca. 55 km ENE from the nearest known populations in McMinn County, Tennessee, and verify Huheey and Stupka's (1967, Amphibians and Reptiles of Great Smoky Mountains National Park. Univ. Tennessee Press, Knoxville. 98 pp.) speculation that this species eventually might be found within the Park. Although generally considered absent from east Tennessee, this species might be more widespread than presently indicated and occur in other cove valleys adjacent to nearby mountainous regions.

Collections were made under permits from Great Smoky Mountains National Park (GRSM-98-031) and the Tennessee Wildlife Resources Agency (No. 1103).

Submitted by **KELLY J. IRWIN**, **C. KENNETH DODD, JR.**, and **MARIAN L. GRIFFEY**, U.S. Geological Survey, Florida Caribbean Science Center, 7920 NW 71st Street, Gainesville, Florida 32653, USA.

SCINAX RUBRA. PUERTO RICO: TOA BAJA: SABANA SECA: wetland area known as Ciénaga de San Pedro, 2.9 km, Rt. 867 within the North Tract sector of the U.S. Naval Security Group Activity (18°27'30"N, 66°12'30"W). 12 November 1998. Neftalí Rios-López. Museo de Biología. Universidad de Puerto Rico-Recinto de Río Piedras (UPRRP 5753, 5755–58). Verified by Rafael L. Joglar. New record for the north-central part of Puerto Rico. Five calling males (mean SVL 28.86 ± 1.19 mm., min. 27.4 mm, max. 30.4 mm) were collected at 2030 h from a flooded area, 2–3 masl, along both sides of a local road within the North Track area. The species is highly abundant within the more than 162 km this wetland covers. These data suggest that the population is established and reproductively active throughout the year. The new geographic area reported herein is the northwesternmost record for the species. The frog was previous reported in Puerto Rico from the Bayamón-Carolina area (Rivero 1998, Los Anfibios y Reptiles de Puerto Rico/The Amphibians and Reptiles of Puerto Rico. Segunda Ed. Editorial Universitaria U.P.R., San Juan. 510 pp.).

Submitted by **NEFTALÍ RIOS-LÓPEZ**, Universidad de Puerto Rico, Recinto de Río Piedras, Departamento de Biología, Apartado 23360, San Juan, Puerto Rico 00931-3360, USA.

SPHAENORHYNCHUS LACTEUS: VENEZUELA: ESTADO AMAZONAS: Mavaca (Yanomami village), Mavaca River, upper Orinoco drainage. 15 September 1981. J. Finkers. Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (EBRG 1947). Verified by Gilson Rivas. Species has been reported in Venezuela from the east edge of the country, in scattered localities in the states of Bolívar, Monagas and Sucre (Hoogmoed and Gorzula 1979, Zool. Meded. Leiden 54[13]:183–216). This specimen from the center of the state of Amazonas extends distribution 600 km to the SW. First state record and southernmost in the country.

Submitted by **CÉSAR LUIS BARRIO**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, 1010-A, Venezuela (email: fudeci@reacciun.ve and cesarlba@yahoo.com), and **RAMÓN RIVERO**, Museo de la Estación Biológica Rancho Grande, MARNR, Apartado 184, Maracay, Aragua, Venezuela.

SYRRHOPHUS CYSTIGNATHOIDES CAMPI (Rio Grande Chirping Frog). USA: TEXAS: LIBERTY CO: Davis Hill State Area, 21.9 (air) km ESE of Cleveland. 7 January 1999. John H. Malone. TCWC 82252. Verified by James R. Dixon. First specimen documented from Liberty County (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp; and Dixon 1996, Tex. Herpetol. Soc. Spec. Publ. No. 2). The specimen was collected during a herpetofaunal inventory for the Texas Parks and Wildlife Department under the authority of State Park Scientific Study Permit 60-98.

Submitted by **JOHN H. MALONE**, Herpetological Independent Study Group, Texas A&M University, Department of Wildlife and Fisheries Sciences, College Station, Texas 77843, USA.

TESTUDINES

CLEMMYS INSCULPTA (Wood Turtle). USA: MAINE: WALDO CO: Sandy Stream National Wildlife Refuge, 0.83 km N Rt. 139 on Sandy Stream (44°37.221'N, 69°21.102'W). 18 April 1999. Phillip G. deMaynadier. University of Massachusetts Museum (UMA Color Photograph R1075). Verified by Alan M. Richmond. Adult male found basking on sandy riverbank in mature hardwood flood plain forest. New county record (Hunter et al. 1999, Maine Amphibians and Reptiles. Univ. Maine Press, Orono. 252 pp.).

AMPHISBAENIA

AMPHISBAENA ANAEMARIAE. BRAZIL: MINAS GERAIS: Nova Ponte (19°08'S, 47°41'W). September 1995. A. Bernardes. Museu Nacional, Rio de Janeiro (MNRJ 6463; 7212-14); Indianápolis (19°02'S, 47°55'W). October 1995. A. Bernardes. MNRJ 7309. All verified by J. Duarte de Barros Filho. Species was recently described by Vanzolini (1997, Pap. Avulsos. Zool., São Paulo 40[3]: 65–85) from a site in the Serra da Mesa range (14°02'S, 48°13'W), in the state of Goiás, and also reported by that author to occur at Anápolis (16°20'S, 48°58'W) in the same state. Previously known only from those two localities. This report extends the range of the species ca. 310 km south of previous southernmost locality (Anápolis), and represents a new state record.

Submitted by **DAVOR VRCIBRADIC**, Setor de Ecologia, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier, 524, 20550-011, Rio de Janeiro, Rio de Janeiro, Brazil, and **MARCELO SOARES**, Departamento de Vertebrados, Museu Nacional do Rio de Janeiro, Quinta da Boa Vista, 20940-040, Rio de Janeiro, Rio de Janeiro, Brazil.

SAURIA

ANOLIS ALLISONI (Allison's Anole). MÉXICO: QUINTANA ROO: Municipio Othón Pompeyo Blanco, Banco Chinchorro, Cayo Centro, ca. 30 km E Majahual (18°35'N, 87°21'W). June 1996. F. Méndez, H. Gadsden, O. Cuéllar, and R. Rodríguez. Museo de Zoología de la Facultad de Ciencias de la Universidad Nacional Autónoma de México (MZFC 10175–76). Verified by O. Flores-Villela. First positive state and country record. A former record from Isla Cozumel, Quintana Roo, was regarded as questionable by Lee (1996, The Amphibians and Reptiles of the Yucatán Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.) on the basis that no other specimens of the species had been collected at that site. Extends range of species about 150 km N of the closest record on the continent at Half Moon Cay, Belize (Lee 1996, *op. cit.*). The referred specimen and many others (not collected) were found perched on the trunks of coconut palms at heights of ca. 2 m or more.

Submitted by **ADRIÁN NIETO-MONTES DE OCA**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, México 04510, Distrito Federal, México, **HUMBERTO BAHENA-BASAVE**, Dirección de Recursos Naturales, Centro de Investigaciones de Quintana Roo, Chetumal, Quintana Roo 77000, México, and **FAUSTO MENDEZ DE LA CRUZ**, Instituto de Biología, Universidad Nacional Autónoma de México, Apartado Postal 70-153, México 04510, Distrito Federal, México.

CNEMIDOPHORUS SEXLINEATUS SEXLINEATUS (Six-lined Racerunner). USA: WEST VIRGINIA: MORGAN CO: SW entrance of Randolph tunnel (39°35'56"N, 78°23'89"W), ca. 3.0 km SW Doe Gully, along CSX railroad, elev. ca. 165 m. 27 July 1999. Zachary I. Felix and W. Jeffrey Humphries. West Virginia Biological Survey, Marshall University (WVBS 12080–81). Verified by Thomas K. Pauley. Two specimens collected from shrubs along blasted shale outcrop on NW side of railroad tracks, ca. 50 m from entrance of tunnel. Ten additional adults were observed on outcrop and in xeric, open areas on ground. New state record (Green and Pauley 1987, Amphibians and Reptiles in West Virginia. Univ. Pittsburgh Press, Pittsburgh. 241 pp.). Suitable habitat occurs near railroad tracks along the Potomac River in Morgan and Hampshire counties. It is expected that *C. s. sexlineatus* will be discovered in other areas in eastern West Virginia.

Submitted by **ZACHARY I. FELIX** and **W. JEFFREY HUMPHRIES**, Department of Biological Sciences, Marshall University, 400 Hal Greer Boulevard, Huntington, West Virginia 25755, USA, and **W. H. MARTIN**, Route 3, Box 804, Harpers Ferry, West Virginia 25425, USA.

ELGARIA KINGII FERRUGINEA (Rusty Alligator Lizard). MÉXICO: AGUASCALIENTES: Arroyo Ibáñez, Municipality of Calvillo (21°45'06"N, 102°45'41"W) in subtropical scrub and oak forest, 1845 m elev. 23 August 1997. SCINCELLA GEMMINGERI GEMMINGERI (Cope's Forest Ground Skink). MÉXICO: TABASCO: 43 km E Coatzacoalcos (Veracruz), near Río Tonalá. 3 June 1964. Bryce C. Brown. SMBU BCB series 12260. Verified by David Lintz. First record for state of Tabasco (Flores and Gerez 1994, Biodiversidad y Conservación en México, UNAM, México, D. F. P. 318).

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611-7800, USA, **BRYCE C. BROWN**, Strecker Museum, Baylor University, Waco, Texas 76798-7154, USA, **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA.

SCINCELLA LATERALIS (Ground Skink). USA: FLORIDA: Gulf Co: White City. 2 May 1998. K. Krysko and A. Reppas. Verified by F. Wayne King. Florida Museum of Natural History, University of Florida (UF 113012). New county record and first record along the southwestern edge of the Apalachicola River.

Submitted by **KENNETH L. KRYSKO**, Department of Wildlife Ecology and Conservation and Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA (email: kenneyk@flmnh.ufl.edu), **ANTHONY T. REPPAS**, Department of Interdisciplinary Studies, University of Florida, Gainesville, Florida 32611, USA, and **JACK R. TANNER**, P.O. Box 5003, White City, Florida 32465, USA.

SPHAERODACTYLUS MACROLEPIS MACROLEPIS (Big Scale Dwarf Gecko). BRITISH VIRGIN ISLANDS: Carval Rock (0.8 ha island, ca. 2 km SSW from Ginger Island), ca. 18°38'N, 64°49'W. 28 October 1998. Alejandro J. Sánchez Muñoz. USNM 529979–80. Verified by James D. Lazell. Found in litter on a 5–6 m rock ledge below two *Coccoloba unifera* trees. New island record.

Submitted by **ALEJANDRO J. SÁNCHEZ MUÑOZ,** P.O. Box 502218, Saint Thomas, Virgin Islands 00805, USA, and **GORDON H. RODDA**, United States Geological Survey, Midcontinent Ecological Science Center, 4512 McMurry Avenue, Fort Collins, Colorado 80525-3400, USA.

TEIUS SUQUIENSIS (Lagartija Verde). ARGENTINA: CÓRDOBA: Departamento General San Martín, Villa María (32°25'S, 63°15'W). 31 December 1997 and 6 December 1998. C. Rozzi Giménez and F. Gallego. Colección de Vertebrados, Universidad Nacional de Río Cuarto, Río Cuarto, Córdoba, Argentina (ZVUNRC 4246 and 4665). Verified by R. A. Martori. Specimens extend the known range at least 100 km SE (following the riparian margins of the Río Tercero) from previously cited localities (Ávila and Martori 1991, Trop. Zool. 4:193–201).

Submitted by **CRISTINA ROZZI GIMÉNES** and **FERNANDO GALLEGO**, Departamento de Ciencias Naturales, Universidad Nacional de Río Cuarto, 5800, Río Cuarto Córdoba, Argentina.

VANZOSAURA RUBRICAUDA. ARGENTINA: CÓRDOBA: Departamento Punilla, Villa Carlos Paz (31°25'S, 64°21'W). 1 January 1999. F. Gallego. Colección de Vertebrados, Universidad Nacional de Río Cuarto, Río Cuarto, Córdoba, Argentina (ZVUNRC 4666). Verified by R. A. Martori. *Vanzosaura rubricauda* is a rare

lizard in Córdoba. Localities of record are Cruz del Eje, El Sauce, Orcosuma, Serrezuela, Mancha and Cabana (Gallardo 1969, Neotropica 15[47]:73–81). Specimen constitutes the first record for the Valle de Punilla, and extends the distribution 45 km SW of previous localities.

Submitted by **FERNANDO GALLEGO**, Zoologia Vertebrados, Universidad Nacional de Río Cuarto, Agencia Postal 3, 5800, Río Cuarto, Córdoba, Argentina.

SERPENTES

CONIOPHANES IMPERIALIS IMPERIALIS (Black-striped Snake). MÉXICO: PUEBLA: Tuzamapan de Galeana, 1.25 km N Tetelilla de Islas (20°06'N, 97°33'W), ca. 160 m elev. 21 February 1997. Sol de Mayo A. Mejenes-López. Colección Nacional de Anfibios y Reptiles, Instituto de Biología, UNAM (IBH 12200, formerly SMML 78). Verified by Luis Canseco Márquez. Young female found under stone in secondary vegetation near tropical moist forest. First record for Puebla; extends range ca. 50 km airline SW of the closest known locality at Poza Rica, Veracruz, reported by Pérez-Higareda and Smith (1991, Ofidiofauna de Veracruz, Análisis Taxonómico y Zoogeográfico. Publs. Espec. Inst. Biól. UNAM 7, 122 pp.).

Submitted by **SOL DE MAYO A. MEJENES-LÓPEZ, FERNANDO MENDOZA QUIJANO,** Instituto Tecnológico Agropecuario No. 6, Km 5.5 Carr, Huejutla-Chalahuiyapa, Apartado Postal No. 94, Huejutla de Reyes, C P. 43000, Hidalgo, México (e-mail fmendoza@mail.ibiología.unam.mx), and **CAROLINA MADERO VEGA, ADA KARLINA MOLLEDA CONTRERAS**, Escuela de Biología, BUAP, Edificio 76, Unidad de Ciencias, Ciudad Universitaria, Avenida San Claudio y Boulevard Valsequillo, Col. HYPSIGLENA TORQUATA (Night Snake). USA: NEW MEXICO: HARDING Co: Kiowa National Grasslands, Mills Canyon Campground, 11.3 air km N and 16.1 air km W jct. New Mexico Rt. 120 and New Mexico Rt. 39 at Roy. SE 1/4 Sec 15, T21N, R24E. 1 June 1999. Terry Hibbitts. University of New Mexico Museum of Southwestern Biology (MSB 61279). Verified by W. G. Degenhardt. New county record (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **TERRY HIBBITTS**, 602 Hilltop Circle, Wylie, Texas 75098, USA, **ANDREW R. WILDS**, 815 North A Street, Apt. 3, Silver City, New Mexico 88061, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

LACHESIS MUTA RHOMBEATA (South American Bushmaster). BRAZIL: CEARÁ: Serra de Baturité, Santana, Pacoti municipality (4°14'02.8"S, 38°53'09.1"W), 800 m elev. July–August 1990. D. M. Borges. Universidade Federal do Ceará (UFC 2064, female with eggs; UFC 2065, young male). Verified by F. L. Franco and D. Fernandes da Silva. First state record; extends known distribution ca. 550 km airline west of previously known range within Atlantic Forest in Rio Grande do Norte or Paraíba to the state of Rio de Janeiro (Campbell and Lamar 1989, The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York. xii + 425 pp.; Zamudio and Greene 1997, Biol. J. Linn. Soc. 62:421–442).

Submitted by **DIVA MARIA BORGES-NOJOSA**, and **JOSÉ SANTIAGO LIMA-VERDE**, Universidade Federal do Ceará, Caixa Postal 52.856, 60.151-970, Fortaleza, Ceará, Brazil (email: dmborges@ufc.br).

LEPTOTYPHLOPS DULCIS (Texas Blind Snake). USA: NEW MEXICO: OTERO Co: found alive in building at 2507 North White Sands Boulevard (Alamogordo), SW 1/4 Sec 18, T16S R10E,

105°57'30"N, 32°55'00"W. 18 May 1999. Carl R. Braziel. University of New Mexico Museum of Southwestern Biology (MSB 61409). Verified by W. G. Degenhardt. New county record (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **GEOFFREY C. CARPENTER**, New Mexico Natural Heritage Program, Southern New Mexico Office, 7 Orchard Road, La Luz, New Mexico 88337, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

NERODIA ERYTHROGASTER NEGLECTA (Copperbelly Water Snake). USA: ILLINOIS: WAYNE CO: Bedford Twp. (Sec. 25, T1N, R7E). 27 April 1999. J. W. Walk and T. Esker. Southern Illinois University voucher number R03161. Verified by S. Ballard. The tail of this specimen was dropped by a perching Red-tailed Hawk. There is some chance that this *Nerodia* may have been taken from a different area and brought into the county via the raptor, but this is unlikely due to the highly territorial nature of Red-tailed Hawks during this part of the breeding season. Peterson (1979, Wisconsin Dept. Nat. Resour. Tech. Bull. No. 111) found the spring home ranges of male Red-tailed Hawks to be a maximum of 179 ha and females to be more restricted than that of males. This range falls well within Wayne County leaving little evidence that it came from elsewhere. Specimen extends the known distribution of *N. erythrogaster neglecta* one county to the north and is ca. 48 km from any known population of this federally proposed threatened snake (Blanford and Brandon 1995, Final Rep. Illinois Dept. Nat. Resources).

Submitted by **DANIEL J. OLSON** and **JEFF W. WALK**, Department of Natural Resources and Environmental Sciences, University of Illinois, Urbana, Illinois 61801, USA.

NERODIA SIPEDON SIPEDON (Northern Water Snake). USA: ILLINOIS: WAYNE CO: Elm River Twp. (T1N, R8E, Co. Rd. 1800N). DOR on Elm River Bridge. 27 April 1999. J. W. Walk and T. Esker. Southern Illinois University voucher number R03160. Verified by S. Ballard. New county record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 298 pp.).

Submitted by **DANIEL J. OLSON** and **JEFF W. WALK**, Department of Natural Resources and Environmental Sciences, University of Illinois, Urbana, Illinois 61801, USA.

OPHEODRYS AESTIVUS (Rough Green Snake). USA: ILLINOIS: MACOUPIN CO: 5 km NNW of Mount Olive, 0.3 km W Redwood Road on E Panther Creek Road (NW 1/4 Sec. 22, T8N, R6W, 39°07'24"N, 89°44'48"W). DOR. 10 MAY 1998. Eric C. Axtell. INHS 14862. Verified by Christopher A. Phillips. New county record.

Submitted by **CAROL A. BRYANT**, 7841 South Panther Creek Road, Mount Olive, Illinois 62069, USA (email: cabryant2@aol.com).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). EGYPT: Al Qahirah Governate: El Ma'adi (29°58'N, 31°15'E), 14 km SE of Cairo, run over by bike. July 1992. Jason Auric(a). MVZ 230077. Verified by Gwilym S. Jones. First country record and first record north of subsaharan Africa, extending range 1300 (airline) km NW of nearest locality in Saudi Arabia (Gasperetti 1988, Fauna of Saudi Arabia 9:197), and 3500 km NNW of nearest African locality (Lanza 1983, Monit. Zool. Ital. 18:219). Data include 20 scale rows, 318 middorsals, 10 subcaudals, 168 mm overall length, length/width ratio 56.

Submitted by **V. WALLACH**, Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138, USA.

RHADINAEA HESPERIA (Western Graceful Brown Snake). MÉXICO: AGUASCALIENTES: 2 km S Mesa el Roble, municipality of Calvillo (21°45'11"N, 102°45'44"W), in guava grove and oak forest, 1891 m elev. 15 August 1998. Joel Vázquez-Díaz and Gustavo Quintero-Díaz. Museo de Zoología "Alfredo L. Herrera", Facultad de Ciencias, UNAM (MZFC 11320). Verified by Oscar Flores-Villela. First record for the state of Aguascalientes; extends range ca. 89 km NE of Mezquital del Oro, Zacatecas (Myers 1974, Bull. Am. Mus. Nat. Hist. 153:1–262).

Submitted by **JOEL VÁZQUEZ-DÍAZ**, Departamento de Investigación y Desarrollo Tecnológico, Internacional de Relojes, Arte y Diseño S.A. de C.V. RHADINAEA LAUREATA (Crowned Graceful Brown Snake). MÉXICO: JALISCO: 40 km NW Sayula. 24 June 1967. Brent Brown. SMBU BCB series 67-888, 67-889, 67-890; 50 km NW Sayula. 25 June 1967. Bryce C. Brown. SMBU BCB series 67-968. All verified by David Lintz. First precise record for the state of Jalisco (Myers 1974, Bull. Am. Mus. Nat. Hist. 153:54–57, citing, but not plotting [nor has anyone else ever plotted] a literature record for "La Cumbre de los Arrastrados, Jalisco;" Flores and Gerez 1994, Biodiversidad y Conservación en México. UNAM, México, D. F. p. 321).

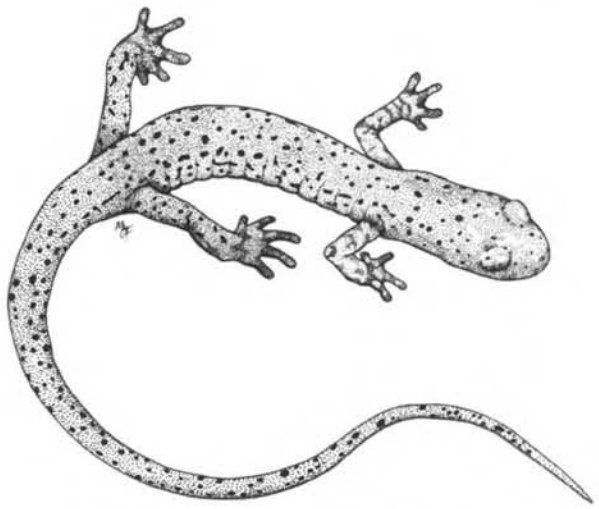
Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611-7800, USA, **BRYCE C. BROWN**, Strecker Museum, Baylor University, Waco Texas 76798-7154, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA.

STORERIA OCCIPITOMACULATA (Redbelly Snake). USA: ILLINOIS: MACOUPIN CO: 3.4 km ENE Benld and N New Mount Olive Lake at Bryant Sawmill (SE 1/4 Sec. 28 T8N, R6W, 39°06'23"N, 89°45'35"W) 4 June 1999. Carol A. Bryant. INHS 14865. Verified by Christopher A. Phillips. New county record. One of two specimens collected raking leaf litter behind maintenance shed.

Submitted by **CAROL A. BRYANT**, 7841 South Panther Creek Road, Mount Olive, Illinois 62069, USA (email: cabryant2@aol.com).

STORERIA OCCIPITOMACULATA (Redbelly Snake). USA: NEBRASKA: HALL CO: 4.5 mi N and 1 mi E Prosser (40°45'N 98°35'W) along Platte River. 6 April 1999. William Beachly. University of Nebraska State Museum (UNSM ZM-16282). Verified by David McLeod. New county record and the third county (along with Dawson and Buffalo) in central Nebraska in which this species has been recorded (Lynch 1985, Trans. Nebraska Acad. Sci. 13:53; Peyton 1989, Herpetol. Rev. 20:13). Extends the central Nebraska distribution 60 km eastward along the Platte River and hints at the possibility that the species will be recorded along the Platte River corridor eastward to the Missouri River, where the only other Nebraska locality for the species is known. As noted by Lynch (1985, *op. cit.*) for another central Nebraska specimen, the spots on

the posterior edge of the head are faint. In the case of this specimen, only the outermost spots are barely evident.



Submitted by **ROYCE E. BALLINGER**, School of Biological Sciences, University of Nebraska-Lincoln, Lincoln, Nebraska 68588-0118, USA, and **WILLIAM BEACHLY**, Department of Biology, Hastings College, Hastings, Nebraska 68901, USA.

THAMNOPHIS SCALIGER (Short-tailed Alpine Garter Snake). MÉXICO: AGUASCALIENTES: municipality of Jesús María (21°59'10"N, 102°34'28"W) in grassland and oak forest. 2 August 1995. Gustavo Quintero-Díaz. Museo de Zoología "Alfredo L. Herrera," Facultad de Ciencias, UNAM (MZFC 12323); 1 km NE Santa Rosa, municipality of San José de Gracia (22°01'10"N, 102°34'50"W) in grassland and oak forest. 10 October 1998. Gustavo Quintero-Díaz. Museo de Zoología Departamento de Biología, Universidad Autónoma de Aguascalientes (UAA-VA 274). Verified by Fernando Mendoza-Quijano and Oscar Flores-Villela. First record for state of Aguascalientes: extends range ca. 103 km NW Matanzas, Jalisco (Rossman and Lara Góngora 1997, Occas. Pap. Mus. Nat. Sci. Louisiana St. Univ. 74:1–14.)

Submitted by **GUSTAVO QUINTERO-DÍAZ**, Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, Avenida Universidad 940, C.P. 20100, Aguascalientes, Aguascalientes, México, **JOEL VÁZQUEZ-DÍAZ**, Departamento de Investigación y Desarrollo Tecnológico, Internacional de Relojes, Arte y Diseño S.A. de C.V. Avenida Aguascalientes, Aguascalientes, México, and **HOBART M. SMITH**, EPO Biology and Museum, University of Colorado, Boulder, Colorado 80309-0334, USA.

VIRGINIA VALERIAE (Smooth Earth Snake). USA: ILLINOIS: Macoupin Co: 3.1 km ENE Benld, N New Mount Olive Lake spillway at Bryant Sawmill (SE 1/4 Sec. 28, T8N, R6W, 39°06'25"N, 89°45'40"W) 2 October 1998. Carol A. Bryant. INHS 14866. Verified by Christopher A Phillips. New county record. Found under fresh sawdust dumped on an oak-hickory forest floor two days previously.

Submitted by **CAROL A. BRYANT**, 7841 South Panther Creek Road, Mount Olive, Illinois 62069, USA (email: cabryant2@aol.com).

New Records of Amphibians and Reptiles for Nassau County, Florida

KENNETH WRAY
Department of Biology, University of Texas at Arlington
Arlington, Texas 76019, USA
e-mail: kpw4791@utarlg.uta.edu

and

RICK OWEN
Department of Wildlife Ecology, University of Florida
Gainesville, Florida 32611, USA
e-mail: bublou@yahoo.com

During a survey of the lower vertebrates of the White Oak Plantation, Nassau County, Florida, USA, several new county records of amphibians and reptiles were collected and deposited into the Florida Museum of Natural History (UF). These records were checked against a database compiled of all Florida specimens in U.S. museum collections (courtesy of Paul Moler) and also records of the Florida Museum of Natural History. While searching in the UF, an overlooked record of *Crotalus horridus* was found by David L. Auth and therefore included in the list below. The following specimen identifications were verified by David L. Auth, Department of Herpetology, Florida Museum of Natural History, Gainesville. All records are USA: Florida: Nassau County.

Amphiuma means (Two-Toed Amphiuma). White Oak Plantation, creek near Windgate Cemetery, Sec. 32, T4N, R26E. 15 July 1997. L. R. Franz, Kenneth Wray, Rick Owen, and Kevin Zippel. UF 106663.

Siren intermedia (Lesser Siren). White Oak Plantation, first culvert south of jct. Brumley Road and Gilman Drive on Brumley Road, Sec. 44, T4N, R25E. 13 July 1997. Kenneth Wray and Rick Owen. UF 106662.

Eleutherodactylus planirostris (Greenhouse Frog). White Oak Plantation, Tortoise Relocation Site, Sec 44, T4N, R25E. 10 June 1997. Cheryl Cheshire. UF 106681.

Hyla chrysoscelis (Gray Treefrog). White Oak Plantation, Gilman Drive, near Kentucky Gate, Sec. 43, T4N, R26E. 30 June 1997. Kenneth Wray. UF 106678.

Chelydra serpentina (Common Snapping Turtle). White Oak Plantation, near center of property, Sec. 43, T4N, R26E. 19 July 1997. Rick Owen and Kenneth Wray. UF 106644.

Trachemys scripta (Slider). White Oak Plantation, near Tortoise Barn, Sec. 43, T4N, R26E. 2 July 1997. Kenneth Wray and Michael Taylor. UF 106643. Extends known range ca. 125 km NNE of the most easterly Florida locality and approximately 25 km S of the nearest Georgia locality (Conant and Collins 1991).

Cemophora coccinea (Scarlet Snake). White Oak Plantation, entrance road, 0.1 mi. southeast of the Little St. Mary's River, Sec. 29/42, T4N, R26E. 4 August 1997. Cheryl Cheshire. DOR.

Diadophis punctatus (Ringneck Snake). White Oak Plantation, jct. Gilman Drive and Rainbow Canal, Sec. 43, T4N, R26E. 4 August 1997. Cheryl Cheshire and Jennifer Staiger. UF 106693.

Heterodon platirhinos (Eastern Hognose Snake). White Oak Plantation, near the Gut Hole, Sec. 24, T4N, R25E. 14 July 1997. Rick Owen and Kenneth Wray. UF 106694.

Crotalus horridus (Timber Rattlesnake). U.S. Rt. 17, 3 miles NW jct. with A1A. August 1976. Dale R. Jackson and Ken Campbell. UF 42563.

Acknowledgments—We thank David L. Auth for his assistance in searching the collection at the Florida Museum of Natural History. We also thank Paul Moler for the use of his database and Dick Franz for his comments on this note.

The following accounts represent new county records for Dimmit and La Salle counties, Texas. All records, except *Coluber constrictor*, were collected from Chaparral Wildlife Management Area as a result of increased baseline inventory and monitoring activities. All identifications were verified by David Cannatella and vouchers have been deposited in the Texas Memorial Museum (TNHC). Justification for new county record status was based upon distribution data from Dixon (1987).

Bufo debilis (Green Toad). Dimmit Co: Chaparral Wildlife Management Area, 8 mi W of Artesia Wells. 13 July 1996. D. C. Ruthven. TNHC color slide 55694. Collected while road-cruising.

Cnemidophorus sexlineatus (Six-lined Racerunner). Dimmit Co: Chaparral Wildlife Management Area, 10 mi W of Artesia Wells. 9 May 1997. D. C. Ruthven. TNHC 56012. Collected in pitfall trap.

Coleonyx brevis (Texas Banded Gecko). LaSalle Co: Chaparral Wildlife Management Area, 6 mi W of Artesia Wells. 2 May 1997. D. C. Ruthven. TNHC Color Slide 55690. Collected in pitfall trap; Dimmit Co: Chaparral Wildlife Management Area, 10 miles west of Artesia Wells. 8 May 1997. D. C. Ruthven. TNHC Color Slide 55693. Collected in pitfall trap.

Coluber constrictor (Eastern Racer). Dimmit Co: U.S. Rt. 83, within city limits of Catarina. 7 May 1997. D. C. Ruthven. TNHC 56015. DOR.

Eumeces obsoletus (Great Plains Skink). LaSalle Co: Chaparral Wildlife Management Area, 6 mi W of Artesia Wells. 6 May 1997. R. T. Kazmaier. TNHC 56010. Collected in pitfall trap.

Leptotyphlops dulcis (Texas Blind Snake). LaSalle Co: Chaparral Wildlife Management Area, 6 mi W of Artesia Wells. 6 August 1996. D. C. Ruthven. TNHC Color Slide 55691. Collected in pitfall trap.

Salvadora grahamiae (Mountain Patchnose Snake). LaSalle Co: Chaparral Wildlife Management Area, 10 mi W of Artesia Wells. 18 April 1997. J. K. Moody. TNHC Color Slide 55692. Collected while road cruising.

Tantilla gracilis (Flathead Snake). Dimmit Co: Chaparral Wildlife Management Area, 8 mi W of Artesia Wells. 3 July 1997. R. T. Kazmaier. TNHC 56014. Collected in pitfall trap.

Tantilla nigriceps (Plains Blackhead Snake). Dimmit Co: Chaparral Wildlife Management Area, 10 mi W of Artesia Wells. 6 May 1997. R. T. Kazmaier. TNHC 56011. Collected in pitfall trap.

Terrapene ornata (Ornate Box Turtle). Dimmit Co: Chaparral Wildlife Management Area, 10 mi W of Artesia Wells. 18 April 1997. D. C. Ruthven. TNHC Color Slide 55695. Collected while road cruising.

The Venezuelan Cordillera de Mérida is a mountain range located in the northernmost Andes in South America, extending some 400 km in a southeastern direction from the Táchira Depression to the Lara Depression, in Western Venezuela (La Marca 1997a). In this extension of land covering semiarid to humid habitats and seasonal and cloud forest to paramo environments, there is an urgent need to document the geographic distributions of reptiles. We had an opportunity to examine specimens of reptiles deposited in the herpetological collection of the Laboratorio de Biogeografía, Universidad de Los Andes (ULABG). These specimens were found to be significant records of previously unrecorded or undocumented (i.e., not supported by voucher specimens) species. Marcos Nattera verified identifications. Taxonomy follows La Marca (1997b).

COLUBRIDAE

Chironius monticola. ESTADO MÉRIDA: Municipio Andrés Bello: Páramo El Tambor, 2930 m elev. 7 October 1987. E. La Marca and J. E. García. ULABG 2057; 17 km from El Paramito, near Las Cruces, road to La Azulita, 1500 m elev. 29 July 1988. P. Soriano. ULABG 2236. This species has been reported from the Andean

States of Táchira (Roze 1966) and Mérida (Dixon et al. 1993:152, 264); however, only the latter is documented by voucher specimens. ULABG 2057 constitutes an elevation record (Dixon et al. 1993, p. 148). Both specimens bridge a distribution gap of more than 1000 km between the Táchira Andes and the Venezuelan coastal range or Cordillera de la Costa (Roze 1966).

Chironius carinatus. ESTADO PORTUGUESA: Municipio Sucre: Biscucuy (9°20'05"N, 69°59'32"W, 455 m elev.). 21 April 1998. L. F. Esqueda and E. La Marca. ULABG 4383.

Dipsas latifrontalis. ESTADO LARA: Municipio Morán: Potrerito de la Virgen, near road intersection to the village of Anzoátegui, in the road Chabasquén–Guarico, 9 km from the Portuguesa-Lara state border (9°35'14"N, 69°51'29"W, 1320 m elev.). 23 April 1998. L. F. Esqueda and E. La Marca. ULABG 4441. First state record and northernmost record for the species, extending the known range about 230 km NE of the type locality.

Imantodes cenchoa. ESTADO MÉRIDA: Municipio Campo Elias: Laguna de Caparú, 900 m elev., 25 km SW Mérida City. May 1984. J. E. García. ULABG 4099. First documented record for the Andes of Venezuela and the state of Mérida (Roze 1966; Lancini 1979; Lancini and Kornacker 1989).

Liophis lineatus. ESTADO MÉRIDA: Municipio Libertador: campus of Facultad de Ciencias Forestales y Ambientales, Universidad de Los Andes, city of Mérida, 1750 m elev. 22 July 1998. J. Achuelo. ULABG 4442; the finding of this species in the city of Mérida is a surprise since all documented records come from lowlands in northern South America (Dixon 1989). The closest locality east of the Venezuelan Andes is the city of Acarigua (Roze 1966); the only record west of the Andes appears to be "Hoya del Rio Negro" in the Sierra de Perijá (Alemán 1953). We do not discount the possibility of an accidental introduction of this specimen into the urban area of Mérida City.

Liophis reginae zweifeli. ESTADO TRUJILLO: Municipio Carache: Hacienda El Rincón, via Potreritos de Cendé-Miquimú, 2275 m elev. 1 December 1989, J. E. García and E. La Marca, ULABG 2765. First state and Venezuelan Andes records (Roze 1966; Lancini 1979; Lancini and Kornacker 1989).

Masticophis mentovarius suborbitalis. ESTADO MÉRIDA: Municipio Sucre: road to La Trampa, near Lagunillas. 25 August 1990. C. Ferrer. ULABG 3047; Municipio Campo Elias: road to Pueblo Nuevo del Sur, near Puente Real. 29 August 1990. C. Ferrer. ULABG 3048. First state and Venezuelan Andes records for the species (Roze 1966; Lancini 1979; Lancini and Kornacker 1989).

Mastigodryas plei. ESTADO MÉRIDA: Municipio Campo Elias: Pueblo Nuevo del Sur, 1500 m elev. 10 May 1989. M. Molinari. ULABG 3050; Laguna de Caparú, 900 m elev., 25 km SW Mérida City. 5 April 1988. A. Mijares. ULABG 3078. First records for the state of Mérida and the Venezuelan Andes (Roze 1966; Lancini 1979; Lancini and Kornacker 1989; Peters and Orejas-Miranda 1970). Southernmost record for this taxon.

Oxybelis aeneus. ESTADO MÉRIDA: Municipio Campo Elias: Laguna de Caparú, 900 m elev. September 1989. Collector unknown. ULABG 2967. The only Venezuelan Andean record in the literature is from Mérida (Roze 1966). This is the second documented specimen and the southernmost locality for the species in the Venezuelan Andes. Extends range ca. 30 km SW of the city of Mérida.

Oxyrhopus petola petola. ESTADO MÉRIDA: Municipio Andrés Bello: La Azulita, 915 m elev. 7 July 1990. M. Molinari. ULABG 2952. First documented record for the state of Mérida (Lancini 1979; Lancini and Kornacker 1989) even though Roze (1966) included this state in a distribution map for the species.

Pseudoboa neuwiedii. ESTADO MÉRIDA: Municipio Caracciolo Parra Olmedo: Tucaní, on road to El Charal. 30 August 1991. Alex Finol. ULABG 3181. To our knowledge, this constitutes the first documented record for the species in the Cordillera de Mérida (Lancini 1979; Lancini and Kornacker 1989; Roze 1966).

Tantilla semicincta. ESTADO MÉRIDA: Municipio Campo Elias: San Juan de Lagunillas. 12 March 1996. B. Hernández. ULABG 4195. First documented record for the species in the Cordillera de Mérida (Lancini 1979; Roze 1966), even though Lancini and Kornacker (1989) indicated that the species occurs in the northern Venezuelan Andes and provided a distribution map for the genus which included the Andean states of Mérida and Trujillo. This is also the southernmost documented record for the species in the Venezuelan Andes.

VIPERIDAE

Bothrops venezuelensis. ESTADO LARA: Municipio Morán: near mountain stream 3 km on road Guarico-Chabasquén, 1270 m elev., 9°33'24"N; 69°52'52"W. 23 April 1998. L. F. Esqueda, A. Markezich, and E. La Marca. ULABG 4443. First documented state record for the species (Campbell and Lamar 1989:224; Lancini 1979:209; Lancini and Kornacker 1989:289; Roze 1968).

ANOMALEPIDIDAE

Liotyphlops albirostris. ESTADO MÉRIDA: Municipio Libertador: Mérida, 1600 m elev. 12 May 1994. M. Molinari. ULABG 3925. Lancini and Kornacker (1989) indicated that this species occurs in the Distrito Federal, and in the states of Miranda and Mérida; they also illustrated a distribution map for the genus which included the Andean states of Mérida, Táchira, and Trujillo. Nonetheless, this is the first confirmed record for the entire Venezuelan Andes, and the southernmost locality for the species.

AMPHISBAENIDAE

Amphisbaena alba. ESTADO TRUJILLO: Municipio Carache: on road between Silos de Monay and Carache, ca. 2 km from crossroad to Chejendé, 300 m elev. 1 December 1989. E. La Marca and J. García. ULABG 2704; Loma de Bonilla, 8 km Carache, 1400 m elev. 1 December 1989. E. La Marca and J. García. ULABG 2705; vicinities of La Playa, between La Playa and La Concepción de Carache, 1175 m elev. 20 December 1989. E. La Marca and J. García. ULABG 2854. First records for the state of Trujillo.

GYMNOPHTHALMIDAE

Bachia heteropa. ESTADO MÉRIDA. Municipio Andrés Bello: La Azulita, 1000 m elev. 1 April 1990. M. Molinari. ULABG 3064. First record for the state of Mérida and the Venezuelan Andes (Donoso-Barros 1968; Peters and Donoso-Barros 1970).

TEIIDAE

Ameiva ameiva praesignis. ESTADO TRUJILLO: Municipio Carache: vicinities of La Playa, between La Playa and La Concepción de Carache, 1175 m elev. 20 December 1989. J. García and E. La Marca. ULABG 2855. First voucher specimen for the state of Trujillo and the Venezuelan Andes.

Acknowledgements.—Partial funding for field work that yielded these collateral results were provided to ELM by the Venezuelan Consejo Nacional de Investigaciones Científicas y Tecnologicas (CONICIT) through grant S1-2053, the Consejo de Desarrollo Cientifico, Humanistico y Tecnologico de la Universidad de Los Andes (CDCHT-ULA) through grants Fo-223-89, Fo-263-91 and C-564-92; and the National Geographic Society grant No. 6176-98, as a co-investigator.

The second year of the volunteer-supported Georgia Herp Atlas, sponsored by the Georgia Department of Natural Resources, was again very successful. Participants from across the state submitted distributional information on a wide variety of reptiles and amphibians. Records reported herein are substantiated by specimens or good quality photographs. A host of previously published materials was used to determine the new county records for each species listed below (including Jensen and Moulis 1997, Lacy 1997, and Williamson and Moulis 1994). All specimens and photographs were deposited in the University of Georgia Museum of Natural History (UGAMNH), Savannah-Ogeechee Canal Museum (SOCM), or at the University of Missouri–Columbia (UMC), as indicated. UGAMNH specimens and photographs were verified by either M. Elizabeth McGhee or the late Joshua Laerm, those at SOCM were verified by Gerald K. Williamson, and the one specimen residing at UMC was verified by Richard E. Daniel.

CAUDATA

Ambystoma maculatum (Spotted Salamander). CLAYTON Co: near confluence Wallis Creek and Flint River (33°28'N, 84°23'W). 5 February 1997. S. Graham. SOCM 1352. MONROE Co: Georgia Rt. 18, 10.3 km NE Bolingbroke (33°06'27"N, 83°47'52"W). 21 November 1997. M. P. Wallace and R. A. Moulis. SOCM 500. POLK Co: Cove Springs Road near Polk-Floyd county line (34°01'31"N, 85°15'35"W). March 1995. S. Sorrells and J. Stewart. SOCM 1353. TAYLOR Co: ca. 50 m N Georgia Rt. 96, 4.0 km W jct. with Georgia Rt. 137. 25 February 1997. J. B. Jensen. UGAMNH 37071.

Ambystoma opacum (Marbled Salamander). CAMDEN Co: Maple/gum pond 5.8 km NW Waverly (31°07'21"N, 81°46'40"W). 2 April 1997. G. K. Williamson and R. A. Moulis. SOCM 127. CLAYTON Co: near South Hampton Court, Jonesboro (33°28'04"N, 84°22'49"W). 11 January 1997. S. Graham. SOCM 1354. COLUMBIA Co: Brezelia Road, Grovetown (33°26'47"N, 82°12'36"W). 1 August 1997. M. Hogue and C. Hogue. SOCM 1355. EARLY Co: Shackleford-Williams Preserve (The Nature Conservancy) near Hilton. 25 January 1997. J. B. Jensen, D. Stevenson, and K. Tassin. UGAMNH 32444. JASPER Co: Charlie Elliott Wildlife Center, Shepard Creek area. 27 May 1997. J. B. Jensen. UGAMNH 37072. MERIWETHER Co: Flint River area off Georgia Rt. 18 (32°59'22"N, 84°31'45"W). 3 May 1997. M. P. Wallace, R. A. Moulis, R. S. Redmond, and J. M. Waters. SOCM 0148. PIKE Co: Georgia Rt. 362 at Flint River (33°10'19"N, 84°30'21"W). 3 May 1997. R. A. Moulis, R. S. Redmond, J. M. Waters, and M. P. Wallace. SOCM 0145.

Ambystoma talpoideum (Mole Salamander). EARLY Co: Shackleford-Williams Preserve (The Nature Conservancy) near Hilton. 25 January 1997. J. B. Jensen, D. Stevenson, and K. Tassin. UGAMNH 32445. MERIWETHER Co: County Road 327 at White

Oak Creek (33°07'21"N, 84°31'13"W). 3 May 1997. R. A. Moulis, R. S. Redmond, J. M. Waters, and M. P. Wallace. SOCM 0146. RANDOLPH Co: ca. 100 m SW Georgia Rt. 41, 1.1 km SE County Road 125. 10 April 1997. J. B. Jensen. UGAMNH 37069. WORTH Co: 0.5 km S County Road 118, 1.3 km W County Road 28. 7 April 1997. J. B. Jensen. UGAMNH 37070.

Ambystoma tigrinum tigrinum (Eastern Tiger Salamander). CRISP Co: Georgia Veterans State Park, 0.2 km SE jct Claypit Rd & Ferry Landing. 9 January 1997. J. B. Jensen. UGAMNH 32454. RANDOLPH Co: ca. 100 m SW Georgia Rt. 41, 1.1 km SE County Road 125. 10 April 1997. J. B. Jensen. UGAMNH 37068.

Amphiuma means (Two-toed Amphiuma). BURKE Co: Yuchi Wildlife Management Area, 0.35 km E Daniel Landing (33°06'21"N, 81°40'15"W). 29 March 1997. A. Davis, Jr., D. Stevenson, and M. Hohmann. SCHLEY Co: Big Muckalee Creek at Georgia Rt. 153 (32°10'50"N, 84°22'06"W). 1 October 1997. R. A. Moulis and G. K. Williamson. SOCM 483.

Desmognathus auriculatus (Southern Dusky Salamander). STEWART Co: Hodchockee Creek off Georgia Rt. 27 (32°03'08"N, 84°46'36"W). 4 May 1997. R. A. Moulis, M. P. Wallace, R. S. Redmond, and J. M. Waters. SOCM 206–7.

Desmognathus conanti (Spotted Dusky Salamander). JASPER Co: Charlie Elliott Wildlife Center, Pittman Creek. 24 May 1997. J. B. Jensen. UGAMNH 37074-75.

Eurycea cirrigera (Southern Two-lined Salamander). CLAYTON Co: South Hampton Court, Jonesboro (33° 28'04"N, 84° 22'49"W). 4 February 1997. S. Graham. SOCM 1356. DECATUR Co: Pennahatchee Creek at County Road 62 (32°05'43"N, 83°55'03"W). 12 September 1997. R. A. Moulis and J. M. Waters. EARLY Co: Shackleford-Williams Preserve (The Nature Conservancy) near Hilton. 25 January 1997. J. B. Jensen, D. Stevenson, and K. Tassin. UGAMNH 32446. JOHNSON Co: Ohoopee River at County Road 174, Pullen Bridge (32°37'04"N, 82°36'44"W). 7 September 1997. R. A. Moulis and J. B. Blue, Jr. SOCM 402–3. JONES Co: Piedmont National Wildlife Refuge, 8.2 km E-ENE of East Juliette (33°08'23"N, 83°41'40"W). 21–22 November 1997. R. A. Moulis and M. P. Wallace. SOCM 501, 507. SCHLEY Co: Buck Creek at County Road 131 (32°18'10"N, 84°20'27"W). 1 October 1997. R. A. Moulis and G. K. Williamson. SOCM 474–5; and Big Mucklee Creek at Georgia Rt. 153 (32°10'30"N, 84°22'06"W). 1 October 1997. R. A. Moulis and G. K. Williamson. SOCM 479–80. STEWART Co: artesian well off Georgia Rt. 39 (32°08'18"N, 84° 51'00"W). 4 May 1997. R. S. Redmond and M. P. Wallace. SOCM 0204; and Hodchockee Creek off Georgia Rt. 27 (32°03'05"N, 84°46'36"W). 4 May 1997. R. A. Moulis, M. P. Wallace, R. S. Redmond, and J. M. Waters. SOCM 208. TREUTLEN Co: Ohoopee River at Georgia Rt. 56 (32°28'15"N, 82°26'15"W). 7 September 1997. R. A. Moulis and J. B. Blue, Jr. SOCM 406–7. WEBSTER Co: along western fork Kinchafoonee Creek off Georgia Rt. 45 (31°58'01"N 84°26'54"W). 1 October 1997. R. A. Moulis and G. K. Williamson. SOCM 486.

Eurycea guttolineata (Three-lined Salamander). APPLING Co: 2.4 mi W jct. Georgia Rt. 15 and Altamaha River (31°56'41"N, 82° 23'17"W). 30 August 1996. W. F. Prince. SOCM 1357. CRAWFORD Co: tributary to Ulcohatchee Creek off County Road 85 (32°44'04"N, 84°08'29"W). 28 June 1997. R. A. Moulis and J. M. Waters. SOCM 0215. DOOLY Co: Pennahatchee Creek at Georgia Rt. 27 (32°05'40"N, 83°48'50"W). 12 September 1997. R. A. Moulis and J. M. Waters. SOCM 421–4; Pennahatchee Creek at County Road 62 (32°05'43"N, 83°55'03"W). 12 September 1997. R. A. Moulis and J. M. Waters. SOCM 428–9; and Turkey Creek at County Road 59 (32°06'15"N, 83°56'22"W). 12 September 1997. R. A. Moulis and J. M. Waters. SOCM 433–39. FAYETTE Co: Morning Creek floodplain, just upstream from its confluence with Flint River (33°27'58"N, 84°23'11"W). 26 September 1997. S. Graham. SOCM 1361. GILMER Co: Mountaintown Creek ca. 1.6 km upstream from confluence with Bear Creek (34°49'14"N, 84°33'00"W). 4 July 1997. T. Carroll and L. Carroll. SOCM 1360. JASPER Co: Charlie Elliott Wildlife Center, Pittman Creek 0.8 km downstream of Henderson Road (33°28'30"N, 83°43'20"W). 24 May 1997. B. Rothermel and W. Knapp. SOCM 1359. MACON Co: Flint River at Georgia Rt. 49 (32°17'53"N, W84°02'38"). 12 September 1997. R. A. Moulis and J. M. Waters. SOCM 455–6; and Flint River at Georgia Rt. 127 (32°25'56"N, 84°01'28"W). 12 September 1997. R. A. Moulis and J. M. Waters. SOCM 0447. SPALDING Co: 1.6 km N Georgia Rt. 92 on east side Flint River (33°19'N, 84°23'W). 2 May 1997. E. O'Neill. SOCM 1358. WEBSTER Co: along western fork of Kinchafoonee Creek off Georgia Rt. 45 (31°58'01"N, 84°26'54"W). 1 October 1997. G. K. Williamson and R. A. Moulis. SOCM 487.

Eurycea quadridigitata (Dwarf Salamander). BROOKS Co: Okapilco Creek at Georgia Rt. 33 bridge. 16 May 1997. J. B. Jensen and M. Frick. UGAMNH 37076.

Necturus alabamensis (Alabama Waterdog). MACON Co: Flint River at Georgia Rt. 49 (32°17'53"N, 84°02'38"W). 12 September 1997. R. A. Moulis and J. M. Waters. SOCM 444. SUMTER Co: Lime Creek at County Road 53 (32°02'07"N, 83°59'32"W). 29 June 1997. R. A. Moulis, R. S. Redmond, J. M. Waters, and M. P. Wallace. SOCM 232.

Notophthalmus viridescens viridescens (Red-spotted Newt). GILMER Co: private residence on N. Jones Mill Road, 12.1 km N Ellijay (34°49'N, 84°25'W). 8 June 1997. G. Hyde and K. Hyde. SOCM 1362. MONROE Co: Nongame Wildlife Program office, Rum Creek Drive, Forsyth. 29 April 1997. T. Schneider. SOCM 1363.

Plethodon glutinosus (Northern Slimy Salamander). JASPER Co: along Pittman Creek ca. 0.8 km downstream from Henderson Road, Charlie Elliott Wildlife Center (33°28'30"N, 83°43'20"W). 24 May 1997. J. B. Jensen and W. Knapp. SOCM 1364.

Plethodon grobmani (Southeastern Slimy Salamander). DOOLY Co: Pennahatchee Creek at Georgia Rt. 27 (32°05'40"N, 83°48'50"). 12 September 1997. R. A. Moulis and J. M. Waters. SOCM 425–6.

Plethodon serratus (Southern Redback Salamander). BIBB Co: Forest Hill Road (32°52'50"N, 83°41'40"W). 1 March 1997. P. Minder and B. Minder. SOCM 1368. CLAYTON Co: near confluence Wallis Creek and Flint River (33°28'N, 84°23'W). 5 February 1997. S. Graham. SOCM 1366. POLK Co: Davis Road, Cedartown (34°06'58"N, 85°18'40"W). March 1997. J. Mullen and J. Stewart. SOCM 1367. WALTON Co: private residence on Clarence Odum Road (33°52'04"N, 83°42'05"W). 2 February 1997. W. Knapp. SOCM 1365.

Pseudotriton montanus flavissimus (Gulf Coast Mud Salamander). EARLY Co: Shackleford-Williams Bluff Preserve, ca. 7.0 km SSW Hilton. 26 January 1997. D. Stevenson and K. Tassin. SOCM 111. STEWART Co: Hodchockee Creek off Georgia Rt. 27 (32°03'05"N, 84°46'36"W). 4 May 1997. R. A. Moulis, M. P. Wallace, R. S. Redmond, and J. M. Waters. SOCM 209.

Pseudotriton ruber ruber (Northern Red Salamander). JASPER Co: tributary of Shepard Creek, Charlie Elliott Wildlife Center. 24 May 1997. J. B. Jensen. UGAMNH 37073. Parkville, Victoria 3052, Australia
e-mail: cbanks@zoo.org.au

This book is co-authored by two of the most knowledgable researchers on Philippine amphibians and reptiles who, between them, have published more than 70 papers and books on systematics, ecology, and natural history of Philippine reptiles and amphibians.

Intended as a semi-popular introduction to Philippine amphibians, this book is the first guide to discuss this group exclusively. It covers 78 species of anurans and three caecilians, although the authors acknowledge that approximately ten additional frog taxa have either been, or are in the process of being, described since the book went to press in mid-1998. This highlights the increasing level of attention now being paid to herpetofauna of the Philippine Archipelago.

After a brief introduction to Philippine amphibians, there is a short chapter on how to use the book, followed by the species accounts. These are each divided into three sections: 1) Basic information including snout-vent length (mm), habitat type (explained in more detail in the "How to use" chapter), diet, mode of reproduction, area of most activity (terrestrial, arboreal, etc.), status (endemic, non-endemic or introduced), and frequency of occurrence (rare, uncommon, common or undetermined); 2) Remarks on such aspects as diagnostic features, specific microhabitats and life history, altitudinal range and conservation status; and 3) Geographic range in the Philippines and Asia. The information in the first and third sections is presented in telegraphic style. The book concludes with a short list of selected references and indices of common and scientific names.

This book is designed for the general reader and "students of biodiversity." If one is seeking more detailed morphological data or habitat descriptions of Philippine amphibians, the earlier publications by Alcala (1986) and Inger (1954) will be more useful. Nevertheless, the new book covers considerably more taxa tha these earlier volumes, with two additional caecilians and thirteen additional frogs in comparison to Alcala (1986). It is also the first book to present such a large number of color photographs of Philippine amphibians.

The book has good production values, is readable, and is a size that easily fits into a good-sized pocket or any day-pack. Hopefully it will help to make the broader wildlife and conservation community more aware of Philippine amphibians and the threats they face. Indeed, a recent assessment of all species suggests that as many as 40% are threatened to some degree (Banks 1999). Significantly, the book is the second to be published on Philippine wildlife and environments by a Filipino publisher within the last year, a welcome trend and one that I hope continues.

Whether one is doing a serious field study on Philippine frogs, or is merely interested in knowing more about Philippine wildlife, this is a book that belongs on the shelf.

Amphibian decline is one of the most troublesome environmental issues of the last decade and, as with many other environmental issues, the cause and even the extent of the problem are not understood. Many researchers are now beginning to realize that a major impediment to understanding amphibian decline is the lack of sufficient baseline information by which to compare current apparent trends. Part of the problem is that many amphibian populations may undergo large inflations and contractions in size depending on short-term local and regional climatic fluctuations. An apparent decline, for example, may actually be a "deflation" (or contraction) of an unusually large ("inflated") population. Clearly there is a need for more information about baseline natural history and population biology of amphibians everywhere. This book is a welcome attempt to help fill this need.

The book grew out of the first meeting (1994) of the DAPTF Central Division at St. Mary's University's Reis Biological Station in St. Louis, Missouri. It presents available information on the status of midwestern amphibians with the explicit purpose of assessing the current situation and providing a useful reference for future studies. The book is large, carefully organized, and includes, in addition to an introduction and conclusion, 42 chapters divided among six sections: landscape patterns and biogeography (five chapters), species status (10 chapters), regional and state status (10 chapters), diseases and toxins (four chapters), conservation (seven chapters), and monitoring and application (six chapters). The book is obviously the product of a gargantuan effort, to say the least, and the editor and authors should be congratulated.

As in any edited book with contributed chapters, however, the quality of the contributions ranges from truly excellent to disappointingly poor. The most useful parts of the book are those that include distribution maps, historical data, and methodologies. An example of an outstanding chapter in this regard is a chapter by Michael J. Mossman et al. which reports the results of a study of long term trends in Wisconsin frog and toad populations. A no-nonsense chapter by Ralph A. Pfingsten consists basically of a series of 42 updated distribution maps of the amphibians of Ohio. For those interested in geographic information systems in relation to landscape ecology and spatial modeling, I can recommend a truly excellent chapter by Anthony Krzysik. Unfortunately, salamanders (which are somewhat more diverse, though less widely distributed, than anurans in the Midwest) get short shrift in this book, and it is not clear whether this is mostly because of lack of information or interest, or both. If salamander decline is a neglected area then this is a clarion call to herpetologists to fill this gap.

My attention was particularly drawn to the chapters on amphibian diseases and deformities, partly because of the inviting cover photograph and frontispiece illustration of deformed frogs with supernumerary limbs, but also because this is an area of my own current research interest. The chapter on diseases by Sandra A. Faeh et al. seemed to be fairly comprehensive in breadth but disappointingly short on details. The authors are to be forgiven, however, since it would have taken an entire book to have done this topic justice.

Nevertheless, I thought the coverage of helminth parasites was astonishingly inadequate since trematodes have been specifically implicated as a major cause of amphibian deformities (Sessions and Ruth 1990), and the evidence has recently grown stronger (Johnson et al. 1999; Sessions et al. 1999).

Much more disappointing was the chapter on deformities by Judy Helgen et al. of the Minnesota Pollution Control Agency (MPCA). Although generously billed by the editor as "an extensive account of the nature of Minnesota northern leopard frog limb and eye malformations", this is one of the weakest chapters in the whole book, both in organization and scope. This is unfortunate because it is the one most likely to attract the attention of non-specialists because of the recent prominence of "deformed frogs" in the media (not to mention the cover illustrations). The authors present no tables of data, almost no indication of frequencies, no serious attempt at analysis, and no review of possible developmental mechanisms, even though these are available specifically for supernumerary limbs both from laboratory experiments (Bryant et al. 1981) and in natural populations of amphibians (Sessions and Ruth 1990). Instead, the authors present a series of anecdotal descriptions of individual frogs and their deformities. To make matters worse, the authors make no attempt to use current terminology from studies of amphibian limb development and regeneration, thus it is difficult to place their observations within the context of the available research literature, not to mention possible developmental mechanisms. The authors consider a wide range of possible causes, including various toxic chemicals, endocrine disrupters, and chromosome rearrangements, but there is no attempt to sort through the possible causes in terms of how they best fit the actual observed deformities. Interestingly (to me, at least), the authors provide little discussion of parasites, even though the role of trematode cyst infection in the induction of the same kinds of deformities as seen in Minnesota was established nearly a decade ago (Sessions and Ruth 1990). They correctly point out, however, that what is needed is to determine empirically whether parasites can cause the observed malformities in the lab. This has now been done (Johnson et al. 1999).

Among the take-home lessons of the book is that the clearest cause of amphibian disappearances is destruction of habitat. There can be little disagreement, for example, that draining of wetlands for housing developments can result in the overt elimination of amphibian populations. Much less understood is the role that chemical pollutants, including pesticides, are having on regional amphibian distribution and health. Least understood (although in many ways the most ominous) is the role of global environmental phenomena such as increased ultraviolet irradiation as a consequence of ozone depletion.

Another important take-home lesson concerns the shifting status of different amphibian species. If "amphibian decline" is the icon of current environmental issues, then Blanchard's cricket frog is the icon of current issues in midwestern amphibian conservation. Twenty years ago that icon would have been *Rana pipiens*, but Leopard frogs are apparently on the rebound in the Midwest, for reasons just as mysterious as their original declines. Blanchard's cricket frogs are clearly disappearing at an alarming rate over most of their range in midwestern states and nobody knows why. What are these animals telling us? Are there patterns here? Are amphibian population increases and decreases, like pistons in a healthy engine, a normal aspect of amphibian natural history, or do the observed fluctuations represent the convulsions and sputtering of dying ecosystems? No answers are forthcoming from this book, which is not surprising since it is merely a step in the right direction and we have a long, long way to go. The weaknesses notwithstanding, this book is a valuable positive contribution to our understanding of amphibian natural history in the midwestern U.S., and future biologists will be grateful for its existence. It belongs on the bookshelf of every serious herpetologist.

e-mail: hvoris@fmnh.org

This book is the second edition of a semi-popular review of the biology of marine snakes. It represents a very substantial increase in volume and subject matter over the original edition. It is logically organized, well written and it is largely free of editorial errors. Its coverage of sea snake natural history and biology is broad and thorough. Although the title suggests that the book may concern itself only with the true sea snakes (Hydrophiidae), this is happily not the case. In fact, Professor Heatwole takes an ecological approach and includes coverage of all marine snakes, fossil and living. This approach makes the book infinitely more interesting and allows the reader to appreciate the breadth of ecological ex-

perimentation that several independent snake lineages have undergone.

This new edition is organized into ten chapters and an appendix as opposed to five chapters in the first edition. Because progress has been uneven in different areas of sea snake biology some chapters have warranted expansion into several new chapters while others have simply benefited from new information being incorporated into the existing treatment. Chapter 1, "What are Sea Snakes?," has been strengthened by a well formulated section on the origin and evolution of sea snakes, and Chapter 2, on the distribution and biodiversity of sea snakes, is 80% new material. Although a section within Chapter 2 is titled "Regional Distributions," it is, in fact, essentially a summary of sea snake distributions according to national boundaries. This approach of using political boundaries has serious limitations. For example, Pakistan, India, Sri Lanka, Bangladesh, and Burma are treated as independent elements rather than parts of geographic or ecological regions. This problem spreads over into a large, two-page map (Figure 2.3) showing the number of species occurring in these political regions. Here Sri Lanka, India, and Bangladesh are depicted as having 18, 23, and 12 species of marine snakes respectively. The differences in these numbers are largely due to differences in past collection efforts and differences in the extent of the sea coasts of each region, and they detract the reader from the important "center of origin" message that is the purpose of the map. It is also unfortunate that there was no attempt to summarize species compositions by region, so it is not possible to learn, for example, that perhaps all the 18 "Sri Lanka species" in Figure 2.3 are among the 23 "Indian species." On the other hand, the section on the distribution patterns of Australian marine snakes employs more of a regional analysis and is well done. In addition, Table 2.1 is a commendable attempt at summarizing the adult size, habitat, and food habits of all marine snake species. Chapter 3, "Natural History," has a much expanded treatment of reproduction and development and a comprehensive table that provides a summary of clutch size and sexual dimorphism for nearly all marine snake species. In addition, this chapter summarizes the results of recent studies of the local movements of the olive sea snake (*Aipysurus laevis*) on several reefs within the Great Barrier Reef system. Chapters 4, 5, and 6, on diet, enemies, and population and community ecology, have been updated but remain largely the solid coverages of the first edition. Both chapters 7 and 8 on adaptations to life in salt water and diving adaptations have enhanced illustrations and expanded tables. In particular, Table 8.1 nicely summarizes hematocrit, blood volume, oxygen capacity, and habitat data for a wide range of marine snakes as well as some terrestrial snakes, turtles, crocodilians, and lizards. In addition, a mostly new section describes how both pulmonary and cutaneous respiration are accomplished and how they relate to the submergence cycle. Numerous subjects related to the venoms of sea snakes are treated in Chapter 9. Here the venom apparatus is described and a good, simplified explanation of neurotoxins, myotoxins, hemotoxins, and nephrotoxins is furnished. The last chapter, "Sea Snakes and Humans," has been expanded three-fold in this edition. This segment will be particularly useful to popular writers and producers of film documentaries who always seem to want to include information on how deadly sea snakes are and which snakes are the most dangerous of all. To this end, Table 10 gives fang length, venom yield, mean toxicity, temperament, and fatality information for 25 species of true sea snakes. Table 10.2 goes even further for the thrill-seeking popular readers by providing estimates of the "number of humans that could be killed" by a mean venom yield and a maximum venom yield from 22 marine and terrestrial poisonous snakes.

This edition represents a serious expansion and enhancement of the first edition. Besides the increase in coverage it provides a much greater photographic coverage with the introduction of 29 color plates of good to excellent quality. I highly recommend this volume to both students and teachers of herpetology as well as serious lay readers. Its comprehensive coverage even suggests that a course devoted to the biology of aquatic snakes may soon be an attractive offering.

Treefrogs of Africa, by Arne Schiøtz. Edition Chimaira, Chimaira Buchhandelsgesellschaft GmbH, Friedberger Anlage 14, 60316 Frankfurt am Main, Germany (distributed in the United States by Zoo Book Sales and Bibliomania!). 352 pp. Hardcover. DM 98,– (approx.US $59.00). ISBN 3-930612-24-0.

K. M. HOWELL
P.O. Box 35064, Department of Zoology and Marine Biology
University of Dar es Salaam, Dar es Salaam, Tanzania
e-mail:khowell@twiga.com

At last—a book that covers all of the "tree" frogs (members of the families Hyperoliidae, Rhacophoridae, and Hylidae) of Africa! The name treefrog is itself a misnomer, because in addition to being found on trees, many of these frogs also occur on sedges and grasses. Dr. Arne Schiøtz has used experience gained conducting field work in West and East Africa from the 1960's to produce a book which allows even the uninitiated to quickly gain information, scant as it is in some cases, on this most colorful group of African anurans. There is probably no living herpetologist who has seen more species of African treefrogs alive in the field than Schiøtz. For those species with which he is less familiar, he has admirably summarized the information available in the literature and has obtained color photographs from colleagues, who have also made a very real contribution to the effectiveness of this book.

Throughout the book, Schiøtz's highly personal touch and approach are evident. This is perhaps most obvious in the introductory section in the brief discussion of species concepts. From a very practical point of view, he notes the difficulties in assigning names to taxa described only from preserved specimens and notes his own emphasis is on non-morphological characters such as voice, habitat preference, and calling site.

There are no numbered chapters, but major topics are provided in a table of contents. After introducing the reader to his basic approach, the author discusses various aspects of treefrog distribution, reproduction, vocalization (termed "the love song"), and conservation. A brief section on collection and preservation is followed by a more detailed portion on keeping treefrogs in captivity, and one entitled "how to use this book." A short acknowledgment section follows.

The section labeled "Systematics" is the heart of the book. For each genus, Schiøtz provides a description which includes details of size, color, pattern, skin texture, condition of the pupil, and other morphological characters. Information on development is also provided, including egg deposition, description of eggs, tadpole, tooth formulae of tadpoles, and general ecological notes on the species in the genus are presented. Where required, further comments are provided on problems of naming species and their relationships with others.

Species accounts are then given in detail, often with information on habitat and altitude, and it is here that the contribution of the field experience of the author is most obvious. A description of the voice, usually accompanied by a sonogram, is presented. Black and white illustrations of particular morphological features of interest

are provided, and the distributions are indicated on an outline map. Color photographs by the author or others are usually presented; in the few cases in which these were not available, black and white or color illustrations from other sources are presented.

This book is not simply a guide. Rather, Schiøtz highlights areas where information is missing and does not avoid pointing out where differences of opinion exist over taxonomic treatments at the generic, specific and subspecific levels. For example, in his presentation of members of the genus *Phylictimantis* he notes that four species are currently recognized but that this situation is by no means settled, and that alternatively, they might all be regarded as subspecies of a single species. The most controversial aspect of the book is Schiøtz's treatment of the *Hyperolius viridiflavus* group, in which he notes that there is variation in color pattern which is probably greater than in any other vertebrate group. He further states "It can be argued that since all the forms probably belong to one or a few reproductive continua where clear-cut delimitation between the different forms are lacking the subspecies concept can not be used in this case." He argues that therefore the current subspecies names for this group are used only as a practical shorthand way of distinguishing distinct forms but are treated as vernacular names and that "future workers can then attach them to any species they choose."

There are many positive features of this book; the most outstanding are the color plates and the clear information presented on each species. These photographs and the accompanying figures will greatly assist in the identification of many species of African treefrogs. The maps indicating the distribution of the species in Africa are another useful feature, allowing the reader to gain a continent-wide rather than regional picture of the species distributions. However, the book would have benefited from a tighter review and editing process which would have reduced some basic omissions and errors. Some of these are simply errors of English usage, others indicate a need for systematic proofreading and checking of facts and details.

Given the importance of the photographs and the contributions made by many colleagues with an interest in African treefrogs, it is somewhat surprising that these are not credited consistently, nor is a list of those who contributed photographs and other such material presented. Sometimes the photographer's name appears in capital letters (e.g., Plate 21: SWITAK), and without initials on some occasions but not others (is Loumont on p. 310 the same as C. Loumont on p. 311?), or with institutional affiliation of the photographer in some cases (e.g., Plate 66: R.C. Drewes), but not others. It is also unclear in cases if the illustrations, both photographs and sonograms, have appeared in other publications (e.g., p.39, sonogram of *Chiromantis xerampelina*, MASON is cited but not included in the reference list).

I found a few places where the meaning of the phrasing was unclear: p. 199, "Laurent ...recognizes hybrids between subspecies, which may be saying the same", p. 309, "*Nesionixalus* differs from *Hyperolius* in its large size, larger testicles [sic]." References cited in the text were generally present in the literature section, but Drewes and Altig (cited in text on p. 68) was not listed. On page 177, Schiøtz makes the interesting observation that it is known that juveniles and subadults have very granulated skin in the dry season, while adults have smooth skin; a literature reference would be of interest to the reader here.

For a book which deals with species, the use and citation of names is critical. I found a few typographic errors in which specific names were capitalized or not italicized. In addition, on p. 177, the name *Hyperolius kihangensis* is used, but the document in which it is purportedly published is, as far as I can tell, not strictly a formal publication. On p. 315, a figure is labeled as *Kassina obscura*, but referred to in text as *Paracassina obscura* (the associated distribution map is correctly labeled).

While good color photographs are important as part of the data gathering process, as the author points out, specimens are also needed. It is somewhat surprising that although he discusses in some detail the care of specimens in captivity and the need to obtain the relevant export documents, less emphasis is paid to the equally important need to obtain the relevant research clearances and collecting permits before undertaking fieldwork, and the necessity of depositing voucher specimens in the host country as a means of increasing local capacity for amphibian studies.

Thanks to his willingness to share his considerable field experience and his ability to synthesize and present information, Arne Schiøtz has provided biologists and indeed anyone interested in African treefrogs with an important basic reference on this group. The criticisms mentioned above by no means detract from this book as a pioneering first, as were his earlier studies on West and East African frogs decades ago. Virtually single-handedly, Arne Schiøtz has produced an extremely valuable contribution to African herpetology—at a very reasonable price. It will no doubt generate many further studies, encourage others to generate and test hypotheses, and in the long run, contribute to the conservation of this group of anurans about which Schiøtz expresses deep concern.

Contributions to a "*Herpetologia Arabica*," edited by Uwe Fritz, Jurgen Obst, and Britta Andreas. 1998. Faunistische Abhandlungen des Staatlichen Museums für Tierkunde, Supplement to vol. 21, 182 pp. Softcover. DM 60,– (approx. US $35.00). ISBN 0375-213511.

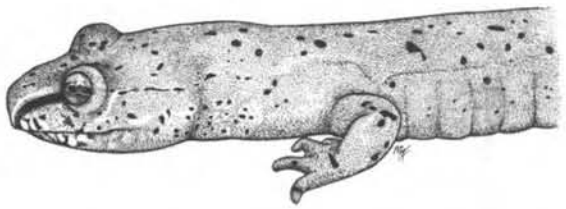
e-mail: asaccus@aol.com

This volume contains 17 papers by 16 of the most active researchers on the herpetofauna of Arabia in the broad sense, i.e., embracing the low countries of Southwest Asia, including Saudi Arabia, Yemen, Oman, the UAE, Syria, Jordan, Iraq, and the Levant. One paper deals with the Taurus Mountains of Turkey, as well. These constitute the proceedings of a meeting March 21–23, 1997 at the Staatliches Museum für Tierkunde in Dresden. Nine papers are in German, eight in English, and all have titles and abstracts in both languages.

As is typical for meetings proceedings, there are shortcomings in terms of coverage, consistency of nomenclature, theme, and style, but the collection is an important contribution to Southwest Asian herpetology, nonetheless. Perhaps of greatest general interest to all students of Southwest Asian zoology are the updated lists of species from Lebanon (in den Bosch), Socotra and Abd el Kuri (Wranik), Israeli desert (Werner), Taurus Mountains, Turkey (Schmidtler), Jordanian turtles (Disi), Jordanian lizards (Disi and Amr), Yemeni and Socotran geckos (Rösler and Wranik). Most of these papers also include remarks on taxonomy, habitat, and distribution. There are also papers with species lists covering more restricted areas: Thumamah Nature Park near Riyadh, Saudi Arabia (Kordges), Barr al Hikman and Masirah Island, Sultanate of Oman (Meinig and Kessler), and Jebel Shams, Oman Mountains (Meinig).

Papers in this volume also contain observations on a number of little-known or little-studied species, e.g., *Uromastyx aegyptia*



(growth and longevity; Brinsre), *Testudo kleinmanni* and *T. graeca* (distribution in the Negev Desert; Brinsre and Buskirk), *Ophisops elegans blanfordi* and *Eirenis barani* (new for Syria; Moravec), and *Agamodon arabicus* (new records; Obst and Wranik) in addition to such observations in the previously mentioned papers. Although no new taxa are described, a number of important range extensions are recorded, e.g., *Testudo kleinmanni* (Brinsre and Buskirk), *Tropiocolotes* cf. *steudneri* (Kordges), several species for the Barr al Hikman peninsula, Oman (Meinig and Kessler), *Ophisops elegans blanfordi* and *Eirenis barani* (Moravec), *Agamodon arabicus* (Obst and Wranik), *Acanthodactylus longipes* and *Eumeces taeniolatus* (Werner). Collectively, the papers in this volume fill many gaps in our knowledge of the habitats of the species covered. Particularly noteworthy in this regard is the paper by Wranik on the natural history of Socotra, and the paper by Disi and Amr on Jordanian lizards. A felicitous addition to the latter is the appendix providing latitude and longitude coordinates for Jordanian localities. Several of the papers include habitat photographs.

Of particular interest to me, is the publication of photographs (black and white) of species rarely or never before photographed, especially in life. These include *Trapelus persicus fieldi* (Kordges), *Pristurus carteri* (Meinig and Kessler), *Eirenis barani* (Moravec), *Tropiocolotes nattereri, T. steudneri, Eumeces taeniolatus, Acanthodactylus longipes, A. opheodurus* (Werner), *Phyllodactylus trachyrhinus, Mesalina balfouri, Mabuya socotrana, Chamaeleo monachus, Pachycalamus brevis, Coluber socotrae, Agamodon arabicus, Coluber thomasi, Bufo arabicus*, and *Euphlyctis ehrenbergii* (Wranik).

Several of the papers concern, or at least touch on, descriptive and/or ecological biogeography (in den Bosch, Disi and Amr, Kordges, Schmidtler, and Wranik). Of these, only Schmidtler's paper on the distributional patterns of the herpetofauna of the Taurus Mountains is devoted specifically to biogeography. This is particularly important, as the mountains of Turkey present a complex pattern of distributions as a consequence of their ecological and geographic history. None of the papers deals with the historical biogeography of Southwest Asia, nor do they incorporate recent techniques whereby phylogenies and geological events are compared.

The entire collection of papers falls under the general rubric of systematics (there are no papers dealing with behavior, physiology, anatomy, toxicology, parasitology, or ecology in the modern sense). However, none of the papers incorporates the molecular, cladistic, and phylogenetic techniques that have recently come to dominate systematics. In large part, this is a consequence of the stage of development of systematics and natural history in this part of the world. We are still in a generally descriptive stage and inadequate access to several areas of Southwest Asia has hitherto prevented the collection of fresh material for biochemical analysis.

The editors are to be commended for their timely publication of these papers, many of which are essential to the establishment of an overview of the herpetofauna of Southwest Asia.

Gyrinophilus porphyriticus danielsi. Illustration by Michael Frick.

Essentials of Reptiles: A Guide for Practitioners, by Thomas H. Boyer. 1998. American Animal Hospital Association Press, Denver, Colorado. vi + 253 pp. Softcover (Spiral-bound). US $46.95 (ISBN 0-941451-65-8).

ANGELO J. L. LAMBIRIS
Department of Zoology, University of Durban-Westville, Private Bag X54001, Durban 4000, South Africa
e-mail: lambiris@pixie.udw.co.za

This update of a previous guide is directed to veterinarians not fully *au fait* with reptile husbandry. The eight chapters discuss matters relating to captive environmental requirements, egg incubation and quarantine; care, medical techniques and diseases of chelonians, lizards, snakes and caimans; reptile anesthesia; and a drug formulary. There is also a list of references and 63 colour photographs illustrating a variety of medical and surgical conditions. Despite the extensive overlap of subject matter in the different chapters, it is probably preferable to review the content by chapter rather than by topic.

As a general statement of the principles of reptile husbandry, the first chapter contains some useful information, but much has been needlessly repeated (frequently almost verbatim) in Chapters 2–6 and much pertinent information on general physiology, behavior and psychology, environmental cues and interactions, biology of stress, and management of wild-caught versus captive-bred animals has been entirely omitted. Helpful as it would be to the layman requiring some guidance on cage design and maintenance, this chapter cannot be considered adequate for the veterinarian who needs a good grounding in reptile biology. I have a few quibbles. Dr. Boyer suggests that it is best to determine the preferred optimal temperature zone for each species, but does not indicate how this should be done. Experimental determinations on captive animals in artificial conditions may not reflect preferences of wild animals in natural surroundings, and it may be helpful to consult museum or university research workers who may have field knowledge of particular species. As with temperatures, so with humidity levels. Although Dr. Boyer recommends PVC tubing for arboreal reptiles to climb on, it is no mechanical or tactile substitute for the real thing. There are some rather curious statements about water bowls, scattered through the various chapters. For example, the suggestion that snakes suffering from dysecdysis "may start swimming and drown" if allowed to soak in too large a container is baffling. It may be clearer to suggest that the bowl should be large enough to accommodate the whole animal comfortably, shallow enough to preclude the risk of drowning. The discussion on ultraviolet light is rather vague, and seems to be of limited value in a guide for the perplexed—some species seem to require ultraviolet light, others can do without it provided that supplements of Vitamin D3 are given (Warwick et al. 1995:13). The papers by Gehrmann (1987) and by Pough (1991) are useful guides to the problems and their solutions in this still poorly known aspect of reptile physiology. Similarly, the section on incubation of eggs is littered with essentially meaningless statements ("Certain species, such as chameleons and some geckos, are often incubated at lower temperatures") and lacks specific detail on important matters such as temperature dependent sex determination.

The chapter on chelonians begins with a "Taxonomy" section, which is really an outline of vernacular nomenclature (paragraph 1), or systematics (paragraph 2). Dr. Boyer does not seem to have sufficiently distinguished between aestivation, from which tortoises may be more or less safely aroused, and hibernation, from which disturbance could well be fatal. The bald statement that "chronic

nutritional problems are typical for most [captive] box turtles yet difficult to appreciate" is unhelpful. How are such deficiencies recognized? How is a corrective regime decided upon? Without anything to go on, how can the given guidelines be interpreted "liberally"? There is a useful, if brief, account of hypovitaminosis A; while it may not be so important a problem as formerly thought in some parts of the world, in other regions it is still common and should always be considered. Mention should be made of the potential hazard of beak overgrowth when providing tortoises with chopped foods. Aquatic chelonians must be provided with adequate land surfaces for basking and other activities. Very large tortoises should not be kept indoors, and clean cement or hay are unacceptable substrata. *Geochelone pardalis* is a savanna, not a desert species. Considering the popularity of African chelonians, some other references than just Boycott and Bourquin would be desirable. The references by Branch (1998), Ernst and Barbour (1989), and Patterson (1987) are invaluable additional references for the veterinarian dealing with African chelonians. There is some useful information on locating and puncturing the radiohumeral venous plexus and the jugular vein. Anterior ventral midline needle insertion for epicoelomic fluid administration may be safer than the scapulohumeral approach, and certainly easier. A Tuohy needle introduced through a skin stab, with the patient held in antero-left lateral recumbency is advised for intracoelomic access. Where acidosis is likely to be a problem, bicarbonate should be administered according to the formula 0.5x(BD.0.3.kg) = mmol bicarbonate required, giving not more than 10 mmol per hour. Red rubber tubing is an irritant, and should not be used for esophagostomies. Plastic tubes should be used for gastric and cloacal washes rather than steel gavage tubes. Putting an open-ended syringe case over a chelonian's head before it can withdraw into the shell, to facilitate nasal irrigation, is one of several ingenious techniques mentioned in this book that was new to me. A simple smear stained with Gram, Methylene Blue and/or Thionine is an effective, inexpensive means of distinguishing between upper respiratory tract infections and other problems such as hypovitaminosis A. Scrubbing abscesses, recommended by Dr. Boyer, could aggravate the problem; gentle sponging is preferred. Topical Gentian Violet, or adding Malachite Green to the water, should also be considered. Maggot cysts can also be flushed with hydrogen peroxide. In repairing shell injuries, gentle sponging rather than scrubbing should be preferred. Sealing fracture sites such as the skin/shell interface with aquarium glue should be strongly condemned - no wonder healing is so slow! Drilling the shell and uniting with suture-ligatures (overlaid with Jelonet, if necessary) is a far better expedient. The surgeon inexperienced in reptile work should be aware that the chelonian plastron is not uniformly thick, and that incision with a trephine and Gigli saw may be slower but safer than an oscillating or circular saw. Three mattress sutures in a 120-degree pattern is safer than two in penile amputations, and cross-clamping, cutting and oversewing with a continuous haemostatic pattern is just as good. I would not wish to wait "several weeks" for resolution of intestinal impaction; a severely compromised patient is a poor surgical risk. Stabilisation and early surgery are probably much safer in the long run.

I have no personal experience of iguana husbandry, but this third chapter seemed to me one of the most useful in the book. One curious omission was a discussion of humidity levels and cycles; these must surely be important, given their natural habitats, with regard to digital and tail necrosis. Giving saline by slow caudal intramuscular drip works wonders in restoring renal perfusion and function in varanids, and presumably the same would hold good for iguanas as well.

In contrast to Chapter 4, that on leopard geckos is surely the least satisfactory in the book. Coverage is so brief and superficial that it hardly merits a separate chapter. Only two and a half pages are devoted to *Eublepharis*, and nearly four address "Feeding Insectivorous Reptiles and Amphibians." (Why amphibians in a reptile handbook?) Indicating calcium/phosphorus ratios "Ca-to-P contents" as "0.1 to 1.2" could be mis-read as indicating ranges rather than ratios—surely "0.1:1.2" would be a more appropriate notation? Newly molted mealworms are much less likely to cause intestinal obstruction than those with well-hardened exoskeletons.

As with chelonians, the taxonomic section in the chapter on snakes is loosely defined, generally unhelpful, and not very comprehensible. The section on housing is certainly not up to South African standards—the suggestion that animals be housed in shoe and sweater boxes, and that a cage "should be almost as long as the snake and half as wide" would bring instant and well-merited prosecution in this country. Patterson (1987) should be consulted for more realistic advice. Much of this chapter repeats earlier ones. The statement that snakes "prefer thawed rodents over freshly killed ones" does not seem entirely in accordance with my own experience; perhaps temperate species behave differently from tropical and subtropical ones. Similarly, while hibernation may be important for stimulating breeding in temperate colubrids, a simple drop in temperature and reduced activity is often sufficient for tropical species. In a supposedly comprehensive handbook, it is irritating to see such comments as "See Barten (1996) for more information on physical examinations," when this is only a two-page article. Cardiocentesis is preferable to buccal vein puncture—it is much less traumatic. One of the most important causes of anorexia has been mentioned so briefly that its importance is simply not apparent—that of psychological stress consequent on inappropriate environmental and handling conditions (e.g., cage size, furnishings, sensory deprivation, etc.) as discussed by Warwick et al. (1995).

In Chapter 6, on caimans, housing is dealt with rather briefly. Despite emphasizing the importance of basking areas in aquaria, and the hygiene problems associated with gravel, there is no constructive advice on how best to manage the problem—again, a serious omission in a handbook which claims to give the practicing veterinarian all he needs! The discussion of infections is very brief, presumably because veterinarians in private practice do not see many caimans. As in snakes, paracentesis cardii is safe and effective for obtaining blood samples, but the surgeon should be aware of how far back the heart is set - the ventricles lie approximately one head length behind the cervico-occipital articulation.

The chapter on anesthesia is disappointingly brief, and rather superficial, with some curious omissions. Premedication is barely mentioned and it should not be assumed that veterinarians unfamiliar with reptiles will not have some questions about such matters. (Aceprom is good for reducing pre- and post-anesthesia excitement, for smooth induction and for reducing the amount of anesthetic needed.) Inhalant anesthetics other than isoflurane are not mentioned, although halothane or halothane/ether are very good as well. The statement that "In reptiles the glottis is open only in inhalation and remains closed otherwise ..." seems functionally untenable. Similarly, the instruction to "gently force" a tube through the glottis is a contradiction in terms. An esophageal stethoscope is very useful for monitoring reptile hearts, especially in chelonians.

The reptile formulary is adequate as far as it goes, but has important gaps and is rather vague in places. "Little is known about long-term drug accumulation, yet the slow metabolism of reptiles often dictates long-term drug usage." The first statement is true, but the second, without extensive discussion, is potentially misleading. It may be more appropriate to say that at lower temperatures the intervals between doses should be extended; but since sick snakes should be kept at higher temperatures than usual to boost the immune system, this may not always be the case. The whole matter is

complex and requires much more in-depth discussion than Dr. Boyer has given. It does, however, highlight how much there is still to learn about even basic chemotherapy in reptiles. It would be desirable to include in the guidelines for specific drugs a clear statement that especially with nephrotoxic drugs adequate hydration is essential and that if necessary bicarbonate may be given to increase pH in order to improve bioavailability and to reduce toxicity. This section is rather brief and uninformative, discussing drug classes rather than specific drugs.

There were some twenty errors in the text—mostly not serious, but careless lapses that should not have crept in; for example, "to allow temperatures to equalize [= stabilize] (p.17); giving food, not a "feeding formula" (p. 55); "caudal tail vein" (p. 87); applying "pressure" [= traction] to the plunger of a syringe when withdrawing blood (p. 87); *Chamaeleo dilepis*, not *dilepsis* (caption to fig. 32); the colon courses between, not through, the kidneys (caption to Fig. 37, renomegaly in *Iguana*).

Although not specifically stated as such, this book is clearly aimed at the American veterinarian; it would be of much more limited scope to practitioners in other parts of the world. The publisher's press release claims that this book is "a comprehensive resource that includes information on the recent advances in the veterinary care of reptiles." It is highly selective, patchy, and incomplete. It is certainly not a compendium, and the all too many referrals to other texts renders the usefulness of the present volume questionable. The book is also said to be "divided by species and covers basic care and nutrition, treatment techniques and common diseases of turtles, green iguanas, reptiles and amphibians (sic!), snakes and caimans." This largely speaks for itself. The book is divided mostly by higher taxa, not by species; amphibians are not included, and reptile coverage is far from complete. Husbandry and some medical aspects are covered, but treatment techniques as such are very superficially discussed. The book is also said to include "numerous helpful illustrations and photographs and an extensive formulary." There are no illustrations in the text at all; the 63 photographs are interesting but not particularly comprehensive; and the formulary, while useful as far as it goes, is by no means comprehensive either. "Practitioners ... can use the book as a reference to teach clients how to house, feed and care for their exotic pets."

In short, this is a book that does not deliver what it promises to its intended readers, and cannot be recommended as a comprehensive professional reference. It would have been far better written (with some modification of the basic content and deletion of those points on medical and surgical practice necessary for the veterinarian) as a general guide for the serious reptile keeper, who would benefit immensely from Dr. Boyer's knowledge of reptile husbandry. The veterinarian requiring specific technical information would be far better served by a judicious selection from the page-and-a-half long list of more definitive texts mentioned by Dr. Boyer—for example, Mader (1996), Frye (1991, 1995), Beynon et al. (1992), and Reichenbach-Klinke and Elkan (1965). The two volumes of *Acta Zoologica et Pathologica* (1984, 1986) dedicated to reptile husbandry and medicine are still an invaluable guide.

PUBLICATIONS RECEIVED

Atlas of Amphibians and Reptiles in Virginia, by Joseph C. Mitchell and Karen K. Reay. 1999. Virginia Department of Game and Inland Fisheries, 4010 West Broad Street, Richmond, Virginia 23230, USA. 122 pp. Softcover. US $7.50. ISBN 0-9671339-0-4.

This publication offers point locality distribution maps for 74 species of amphibians and 61 species of reptiles known to occur within the state. Also included are a history of herpetofaunal exploration in Virginia, a description of Virginia's environmental features, a review of conservation needs, and an extensive bibliography. It is designed to provide a comprehensive source of distributional data for individuals engaged in surveys, monitoring programs, conservation and management, and education. Together with Mitchell's "The Reptiles of Virginia" (1994), herpetologists now have available two excellent compendia of biological data concerning that state's herpetofauna.

Chameleons, Nature's Hidden Jewels, by Petr Neças. 1999. Edition Chimaira, Frankfurt am Main, Germany. North American distributor: Krieger Publishing Company, 1725 Krieger Drive, Malabar, Florida 32950, USA (email: info@krieger-pub.com). 348 pp. Hardcover. US $47.50. ISBN 1-57524-137-4.

This is the English edition of a book originally published in German in 1995 (reviewed in Herpetol. Rev. 28:106–107). Like the original edition, this book provides species accounts for 50 species of chameleons, along with sections on systematics, biology, and herpetoculture. The new edition is also expanded relative to the first, with an updated bibliography of approximately 1000 references, a listing of all recent and fossil species (including primary synonyms, type localities, and distribution), and 323 illustrations and photos (actually more, as several full page illustrations from classic works on chameleons are not numbered), mostly in color. The layout of the book is improved relative to the German original, and the color photos are conveniently distributed throughout the text. The English translation is, unfortunately, rather awkward and perhaps too literal. This and the lack of a general index are the greatest faults of the book. Nonetheless, the book serves as a thorough and current compendium of information on chameleons and will be of interest to both amateur and professional herpetologists.

A Monograph of the Testudinata, by Thomas Bell. 1999. Octavo Corporation, 580 Second Street, Oakland, California 94607, USA (www.octavo.com; info@octavo.com). CD-ROM. US $35.00. ISBN 1-891788-22-1.

This is the first commercially released digital facsimile of a herpetological work by Octavo Digital Editions. The CD presents Bell's classic monograph in its entirety. Included are Bell's original (1832–36) text and 40 plates as well as the additional 21 plates and 16 pages of text by J. E. Gray published in 1872 (previously reprinted in black and white by SSAR in 1970). The entire book, including the covers, has been digitized from a fine colored copy, originally presented by Bell himself, in the collection of the Academy of Natural Sciences of Philadelphia. In addition, this version incorporates a commentary by Kraig Adler that provides information about the author, as well as the illustrator (James de Carle Sowerby) and the lithographer (Edward Lear) whose exquisite plates are responsible for the lasting value of Bell's monograph. Adler also provides information relative to the dating of the original work and a concordance of the names used by Bell and Gray with their modern counterparts. The entire work is in the form of Adobe® Acrobat® PDF files that are compatible with Windows, Macintosh, UNIX, and OS/2 operating systems. The CD is easily searched by a number of methods and thumbnail versions of each pair of facing pages facilitate scanning of the contents. Individual lithographs and/or sections of text, or the entire work, can also easily be printed in color or black and white. Although nothing can replace the original, this CD-ROM provides an affordable facsimile of superb quality that will increase the availability of this rare work to scholars and cheloniophiles.

Amphibians and Reptiles in Colorado, Revised Edition

Geoffrey A. Hammerson

"[A] landmark in the advancement of knowledge concerning the amphibians and reptiles of Colorado, by the state's leading authority on the subject. Expanding and updating his first edition, published in 1982, Dr. Hammerson has produced a book that may well become a standard for regional natural history field guides. I enthusiastically recommend this book to laymen and professionals alike."—Robert C. Stebbins, Professor Emeritus of Zoology and Curator in Herpetology, U.C. Berkeley Museum of Vertebrate Zoology

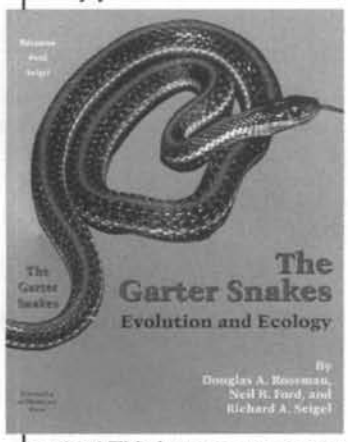
Garden of Readin'

Amphibians and Reptiles of Northern Guatemala, the Yucatán, and Belize

By Jonathan Campbell

Ranging from the enormous and potentially dangerous to the tiny and secretive, about 160 species are illustrated and profiled in this first field guide to the reptiles and amphibians of this diverse region of Central America. This guide is designed for scientists, tourists and armchair travelers. It includes frogs, toads, salamanders, caecilians, turtles, lizards, crocodiles and snakes; notes on where to look for the animals; folklore and adventures; four decades of Campbell's own observations; and English and Spanish identification keys.

400 pages, 176 color and 11 b&w illustrations, maps, glossary, 7 × 10.



$100.00 Hardcover

The Garter Snakes

Evolution and Ecology

By Douglas A. Rossman, Neil B. Ford, and Richard A. Seigel

All 30 recognized species of garter snakes are examined in this first comprehensive review of the genus Thamnophis in nearly ninety years. The book includes a modern key to all species—and for each species, color plates and summaries of the systematics and natural history. It details each species' habitat, distribution, preferred diet, reproductive and population biologies, and captive maintenance, concluding with a discussion of conservation concerns. Written by the world's leading authorities, this appealing book will be highly useful not only to herpetologists but also to conservationists, ecologists, pet owners, and others interested in natural history.

"Garter snakes! And more garter snakes! This keystone coverage will set the herpetological standard for works of this type."—**J. Whitfield Gibbons**, University of Georgia

268 pages, 88 color and 31 b&w illustrations, 28 maps, glossary, index, 7 × 10.

$65.00 Hardcover

Animal Behavior

General Editor: Timothy Halliday

How do birds navigate? Why do bees dance? How do sea anemones fight? Written by a team of international experts, this beautiful book is packed with examples of the activities of all types of animals—mammals, birds, reptiles, insects and fish—as they find shelter and food, attract a mate, care for their young, defend themselves, navigate, and survive the many challenges of life. The relationships animals have with other animals—food, friend, or foe—are a major element in their activities. Animals' behavior is important to the earth's ecological balance, and thus a key to the vitality of the planet.

144 pages, 251 color plates, 22 b&w illustrations, 8½ × 11.

Instructions to Publishers

1. Complete and file one copy of this form with your postmaster annually on or before October 1. Keep a copy of the completed form for your records.
2. In cases where the stockholder or security holder is a trustee, include in items 10 and 11 the name of the person or corporation for whom the trustee is acting. Also include the names and addresses of individuals who are stockholders who own or hold 1 percent or more of the total amount of bonds, mortgages, or other securities of the publishing corporation. In item 11, if none, check the box. Use blank sheets if more space is required.
3. Be sure to furnish all circulation information called for in item 15. Free circulation must be shown in items 15d, e, and f.
4. Item 15h., Copies not Distributed, must include (1) newsstand copies originally stated on Form 3541, and returned to the publisher, (2) estimated returns from news agents, and (3), copies for office use, leftovers, spoiled, and all other copies not distributed.
5. If the publication had Periodicals authorization as a general or requester publication, this Statement of Ownership, Management, and Circulation must be published; it must be printed in any issue in October or, if the publication is not published during October, the first issue printed after October.
6. In item 16, indicate the date of the issue in which this Statement of Ownership will be published.
7. Item 17 must be signed.

Failure to file or publish a statement of ownership may lead to suspension of Periodicals authorization.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700		$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$270

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1999 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

2000 — Universidad Autónoma de Baja California Sur, La Paz, BCS, México, 14–21 June 2000 (Carlos Villavicencio, Chair).
2001 — Indiana University/Purdue University, Indianapolis, Indiana, USA, 26–30 July 2001

Society for the Study of Amphibians and Reptiles
2000 Annual Meeting

together with

American Society of Ichthyologists and Herpetologists

and

The Herpetologists' League

14 – 21 June 2000

Universidad Autónoma de Baja California Sur, La Paz, BCS, México

La Universidad Autónoma de Baja California Sur is located in La Paz, BCS, in the southern part of the Peninsula, in the Gulf of California. Founded in 1535, La Paz is a small and quiet city, known for good drinks and food services.

Keynote Address: "Frogs, Fossils and Phylogeny: A Perspective on the Last 140 Million Years and Prospectus for the Future," by Linda Trueb, The Hepetologists' League Distinguished Herpetologist for 2000 (The University of Kansas).

Symposium: "Ecology and Evolution in the Tropics: Essays in Tribute to Jay Savage." *Organizers:* Maureen A. Donnelly, Florida International University (donnelly@fiu.edu); Brian I. Crother, Southeastern Louisiana University (bcrother@selu.edu); Craig Guyer, Auburn University (cguyer@acesag.auburn.edu); Marvalee H. Wake, University of California, Berkeley (mhwake@garnet.berkeley.edu); and Mary E. White, Southeastern Louisiana University (mwhite@selu.edu).

Symposium: "Partners for Amphibian and Reptile Conservation." *Organizers:* Henry Mushinsky, Department of Biology. University of South Florida. Tampa, Florida 33620-5150, USA; tel. 813-974-5218, fax 813-974-3263: (mushinsk@chumal.cas.usf.edu). Laura Herbeck, North Central Research Station, U.S. Forest Service, 202 Natural Resource Building, University of Missouri, Columbia, Missouri 65211, USA; tel. 573-875-5341 ext. 227. Cynthia Carey. Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA; tel. 303-492-6014.

Symposium: "The Natural History and Evolution of the Herpetofauna of Southern California and Baja California." *Organizers:* Robert Fisher, USGS-Western Ecological Research Center, SDSU Field Stations, Department of Biology, San Diego State University, San Diego, California 92182-4614, USA; tel. 619-594-8026, fax 619-594-2035 (rfisher@sunstroke.sdsu.edu) and Robert Lovich, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA and Department of Biology, San Diego State University, San Diego, California 92182-4614, USA; tel. 619-594-8025 (rlovich@sciences.sdsu.edu).

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day throughout the conference.

Meeting Site: SSAR, HL and CAH will meet in the Hotel Araiza Inn Palmira; palmira@balandra.uabcs.mx; tel. (dialing from USA): 011 52 11216200, fax: 011 52 11216227; International Reservations 1-800-9-ARAIZA, National Reservations 01-800-71-68-777. Other recommended close hotels are: Marina, El Moro, and La Concha (contact details and locational map are provided in the official meeting announcement).

Travel Arrangements: Everyone will need to make their own hotel reservation. The recommended airport is La Paz, but also you can fly into Los Cabos (220 km south), and then rent a car.

Student Travel Award: Ten travel grants of US $200 each will be available for SSAR student members. Refer to page 197 in this issue of *HR* for details.

Student Paper Award: Henri Seibert prizes (US $200 each) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. Refer to the official Meeting Announcement for details.

Social Activities: General Reception at the Municipal Dock, SSAR Auction, SSAR Herp Silent Auction, Beach Barbecue, Graduate Student Reception, and ASIH Banquet.

Multimedia Events: Special Herpetologists' League Illustrated Lecture: "The Amphibians and Reptiles of Baja California and the Sea of Cortés," by Lee Grismer. SSAR Presidential Slide Show (presenters and titles to be announced).

Field Trips: Will be arranged to nearby desert areas and islands.

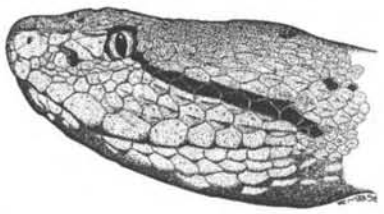
Costs: Preregistration US $185 regular, US $95 student, US $95 accompanying person. After March 15, 2000, costs are US $245, US $135 student.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Further Details: Meeting Announcement and Call for Papers was mailed to all Canadian, U.S., and Mexican members of the participating societies in December 1999. Overseas members wishing to receive this information may do so by contacting Carlos Villavicencio Garayzar, Local Chair, Universidad Autonoma de Baja California Sur. A.P.19-B. La Paz, B.C.S., México. CP23080; (cvilla@calafia.uabcs.mx & ASIH@calafia.uabcs.mx), Tel. & fax: 011-52-1-128-0775. Please visit the meeting web site at www.uabcs.mx/asih for additional and updated information.

About Our Cover:

Stenophis citrinus, recently described by Domergue (1995. Arch. Inst. Pasteur, Madagascar 61[2]:121–122) is a small (ca. 50 cm total adult length), live-bearing Malagasy colubrid known from only a handful of museum specimens. All were collected in the dry, deciduous forests of west-central Madagascar. This recent addition to science is a perfect example of the high rate of new herpetological species still being discovered and described in Madagascar today.



Stenophis (formerly included in the genus *Lycodryas*) is currently comprised of 15 species whose collective range covers the entire country, occupying diverse habitats and microclimates. Little is known of their natural histories aside from their strongly nocturnal activity preferences. While some species are known egglayers, *S. citrinus* has been documented as a livebearer (Vences, Glaw, and Love 1998. Brit. Herpetol. Soc. Bull. No. 64:13–14).

Their slender profiles, bulbous heads, and overall size give *Stenophis* an appearance that is remarkably similar to that of the neotropical tree snakes of the genus *Imantodes*. Snakes of the genus *Stenophis* likewise lead arboreal lives in bushes and trees, but they have also been found on roads at night. Natural prey is presumed to include lizards, although the few live specimens imported from Madagascar to date have refused to accept any of a plethora of potential food items in captivity, with the possible exception of hatchling day geckos (*Phelsuma* sp.) (Chris Estep, pers. comm.).

The cover image was taken by **Bill Love** at the Exotic Butterfly Farm near Mandraka in east-central Madagascar, owned by French naturalist and exporter André Peyrieras. This special rare animal was kindly shown, and subsequently allowed to be photographed, during a 1995 visit while Bill was leading a herp photo tour to that facility for his company **Blue Chameleon Ventures**. The snake's identity was unknown to him at the time since its formal description had not yet appeared. Its purposefully slow movements and spectacular color and pattern were enough to warrant permanent capture on film.

Bill's passion for photography has resulted in his amassing a collection of tens of thousands of slides of reptile and amphibian subjects from all over the world. Supplying herp imagery has become an important aspect of his business. This shot was taken with a Nikon 4004 camera, a Nikon 55 mm macro lens, and a Nikon Macro Speedlight SB-21 on Fujichrome Velvia. The background in this case is merely a convenient clump of foliage and is not intended to represent authentic habitat.

Separation and imaging of Love's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

Atropoides nummifer. Illustration by R. Michael Burger.

SSAR BUSINESS

1999 Annual Meeting: Penn State

The 42nd annual meeting of SSAR occurred from 24 to 30 June 1999 in State Center, Pennsylvania. Once again this year, SSAR met jointly with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists on the campus of Pennsylvania State University. The University and local committee, chaired by Jay Stauffer, hosted 1,150 delegates, of whom 45% were students and 43% women. Most of the meeting's events took place at the Penn Stater Conference Center located near the Penn State campus.

Social Programs

Numerous social events served to counterpoint the scientific presentations at this year's annual meeting. On Thursday evening (24 June), an unsponsored social at the Legends Pub in the Penn Stater Conference Center Hotel served as a convenient gathering locale. A general reception, again held at the Conference Center, provided opportunities for discussions and exchange of ideas at the close of the first full day of the meetings (25 June). The Student Reception served as the only official social event on Saturday, a day largely devoted to student presentations. Additionally, the confines of the meeting site contributed to formation of small social groups and the planning of breaks during the day provided ample opportunities for informal interactions.

On Sunday (27 June), the threat of evening showers did not dampen the atmosphere at the Barbecue Picnic held on the Penn State University campus. Ribs and chicken formed the basis for a meal that had many folks returning for seconds between lively discussions with friends, colleagues, and old acquaintances.

Unusually warm and humid conditions lead to impressive thunderstorms on the evening of the SSAR Auction (28 June). Draconian policies with respect to alcohol distribution on campus cost the Society some money, but an ample supply of beer was avail-

Harry Greene (left) congratulates David Wake for receiving the Henry Fitch Award at the annual banquet. Greene made the presentation on behalf of ASIH, which initiated the Fitch Award in 1998 to recognize excellence in the field of herpetology.

Nate Kley, Al Richmond, and Chris Feldman enjoy the atmosphere at the Barbecue Picnic.

able. The Straub Brewery (Saint Marys, PA) generously donated several barrels of quality, all-grain brew for the event. Active building renovation at the Penn State HUB Ballroom presented interesting logistical problems. Large fans, poor acoustics, and extended walks to facilities did not seem to hinder bidding. Many quality items were offered for consideration and the lively tag-team approach implemented by primary auctioneer David Morafka, assisted by John Moriarty, kept the evening moving briskly. Throughout several days of the meeting, the SSAR Frameable Silent Art Auction raised revenues from bidding on numerous quality art objects. Revenues generated from both auctions approximated $5,000 and will be used to support student travel to future meetings.

Tuesday evening marked the return of the David Dennis-Eric Juterbock-Kraig Adler lavish multimedia presentations. The beauty, artistry, and historical nature of these shows are always crowd pleasing, regardless of how many times you see them.

The close of the meetings was marked by the Banquet, sponsored jointly by all the attending societies. This event allowed for a more refined set of behaviors on the part of the membership in attendance. While members at the Banquet enjoyed the reserved nature of the event, others seeking louder nightlife found it in various clubs and pubs of downtown State College.

Institutional animal care guidelines precluded a live animal exhibit, but the indigenous herpetofauna was available for those willing to investigate local habitats.

Business Meeting

President Hutchison called to order the 42nd Annual Business Meeting of the SSAR at 1500 h in the Presidents I Room of the Penn State Conference Center at the University of Pennsylvania on Sunday, June 27th. He reported that the Presidential Challenge that was initiated last year has been very successful. The challenge was put forward for all past presidents of SSAR to donate $500 each to the Endowment Fund. To date, $6,500 has been raised. He discussed building the endowment so that the society will have more flexibility in the future.

President Hutchison announced that the *Directory of Herpetologists* by Harold Dundee and George Pisani was completed and available at the meetings. Everyone was encouraged to pick up his or her copy. This is a combined listing of all herpetologists from each society (SSAR, HL, and ASIH) and each society provided money for production so that all herpetology members would receive a free copy. Hutchison thanked the two editors for their time and effort. He then announced that he had extracted all of the names of herpetologists of HL and ASIH that were not members of SSAR (978 people). With these names, he initiated a membership drive. All officers of SSAR and several other volunteers were recruited to write a letter to these non-members asking them to join. The hope is that we will gain several new members. New members provide further revenue for activities that the society supports.

Several new appointments were announced including Darrel Frost as ASC representative, Laurie Vitt as SSAR representative to PARC, Theodora Pinou as the Membership Committee Chair, and Lynette Sievert as Elector. In addition, all chairs of committees were reappointed except for the International Cooperation Committee which had accomplished its goals and was disbanded. Marty Crump and the committee were thanked for their efforts. Two resignations were announced: Ellen Censky as Secretary had resigned with the effective date yet to be determined and Rich Seigel would resign as Editor of *Journal of Herpetology* effective 31 Dec 2000. President Hutchison stressed that we need to fill positions with new blood and asked that anyone who was interested in helping the society contact President-elect Julian Lee or him.

The President announced a new committee to oversee publications, the Publications Task Force. The PTF will be comprised of three people and will be charged with keeping the society current with regards to electronic publishing, ethics, etc.

Kraig Adler announced that Mrs. Bailey had donated Joe Bailey's library to SSAR. SSAR will sell the library. Mrs. Bailey asked that the proceeds be used for publishing books and for support of student research. Adler and Steve Busack will be organizing the sale.

Secretary Censky read the proposed amendment to the Bylaws which involved changing the terms of office for President, President-elect and Past President from one year to two year terms, and the terms for Secretary, Treasurer and Publications Secretary from one year to three year terms. The proposal was open for discussion at this meeting and will be put to a vote later in the year.

Secretary Censky presented much of the remaining business conducted at the Board Meeting. The treasurer's report noted that we had a drop in membership for the past year but that the society was on the rebound. There was no logical explanation for the drop. It was announced that Life Memberships would be offered for a one-installment payment of $1250 or four installments of $325. The board approved a 2000 budget of $208,947.

Journal of Herpetology editor Rich Seigel reported that submission rates continued to be extraordinarily high during the past year. There was a record number of 277 submissions in 1998. There were

Hinrich Kaiser, Jan Caldwell, and Laurie Vitt were among the many herpetologists and ichthyologists attending the annual banquet.

SSAR President Vic Hutchison (right) discussed the benefits of holding a future SSAR meeting at Cornell with potential hosts Kelly Zamudio (center) and Harry Greene (left).

signs, however, that submission rates were leveling off. He also reported that the current backlog of 9–12 months to publication should be maintained due to three factors: an increase in the 1999 budget, lower submission rate for 1999, and reduction in costs from Allen Press. *Herpetological Review* editor Bob Hansen also reported that the number of submissions has steadily increased but seems to have leveled off in the past year. The expansion of the journal last year to 64 pages has helped to deal with the increased submissions. Hansen reported several changes to his editorial staff: Liz Johnson (Ad manager), Hal Avery (Associate Editor), and Kathryn Vaughan (Section Editor) resigned. Hansen expressed his appreciation for their long hours and dedication. New appointments include J. Brian Hauge (Section Editor), Joe Mendelson (Associate Editor), and Sharyn Marks (Associate Editor).

The *Catalogue of American Amphibians and Reptiles* report to the board stated that a total of 89 printed pages were produced this year. The 20 accounts consisted of one caecilian, four salamander, two frog, two turtle, six lizard, four snake and one crocodilian accounts. Color plates were included in seven accounts. Contribution and Facimiles editor Kraig Adler reported that two works will be published in 1999: "Lizards of Iran," by Steven C. Anderson and "General Zoology: Volume 3 Amphibia," by George Shaw. There were three books published in 1998: "Biology of the Reptilia, volume 19: Visceral Organs," edited by Carl Gans and Abbot Gaunt, "Contributions to the Herpetology of the Belgian Congo," by Karl P. Schmidt and G. K. Noble, and "The Gigantic Land Tortoises of the Galapagos Archipelago," by John VanDenburgh. Future publications include "Anatomy of the Salamander," by Eric T. B. Francis, "Herpetofauna of New Caledonia and Surrounding Islands," by Aaron Bauer and Ross Sadlier, "Herpetological Illustrations from the Spencer Library, University of Kansas," compiled by Sally Haines, "Amphibians of Honduras," by James R. McCranie and Larry David Wilson, and "Hylid Frogs of Middle America," by William E. Duellman.

A highlight of the meeting was a symposium in honor of Richard Etheridge, recently retired from San Diego State University. Friends, colleagues, and former students later gathered for an evening roast. Shown here, from left to right, are: Jim McGuire, Troy Baird, Lee Grismer, Kevin de Queiroz, Chuck Crumly, Richard Etheridge, Bill Presch, Greg Pregill, Jacques Gauthier, Julian Lee, Brad Hollingsworth, Van Wallach, and Bobby Espinoza.

Herpetological Circulars editor John Moriarty reported that "Lineages of Zoo Herpetologists in the United States," by Card and Murphy will be published in late 1999. "State and Provincial Amphibian and Reptile Publications for the United States and Canada," by Moriarty and Bauer is currently under review and should be published in Spring 2000. "Standard Common and Scientific Names" is finished, as reported by Brian Crother, Chairman of the Common and Scientific Names Committee. Moriarty reported that it should be published late in the year 2000. The *Herpetological Conservation* report to the board stated that work was progressing on Volume 2 "Ecotoxicology of Amphibians and Reptiles."

The Grants-in-Herpetology Committee (M. Dorcas, J. Wicknick, C. Beachy, T. Reeder, P. Ducey, A. Maglia, D. Wilson, D. Kizirian, R. King, J. Mendelson) report stated that there were a total of 51 applicants: Travel (13), Conservation (8), Laboratory (16), Field (17), International (3), and Education (2). Chairman Joe Mendelson noted that previous winners would be discouraged from seeking more funds from these limited resources. The board approved an increase of $1,000 for two additional grants. The annual report of the Kennedy Student Award Committee (R. Andrews, D. Duvall, M. Mendonca, T. Schwaner, R. Gatten, chair) announced the winner of this year's competition, "Predator mediated patch use by tadpoles (*Hyla regilla*): risk balancing or consequences of motionlessness?" by Sarah J. Kupferberg. There were a total of nine manuscripts in competition.

The Student Travel Award Committee (Lance McBrayer) presented 18 awards of $200 each to defray the costs of travel to meetings. In addition, several items for the auction were secured. Chairman Kelly McCoy, Seibert Student Award Committee, reported that there were 53 presentations in competition this year: seven in systematics, 28 in ecology and evolution, 12 in conservation and six in physiology and morphology. The judges were K. McCoy, S. Beaupre, P. Stone, W. Lutterschmidt, and J. Mendelson.

Carlos Villavicencio reported on the 2000 meetings in La Paz, Baja California Sur, México, where SSAR again will meet jointly with HL and ASIH. The dates for the meeting are June 14–20. Several hotels have been reserved. The Araiza Inn Palmira has been chosen as the hotel that will host herpetologists. The Hotel Marina and Hotel La Concha are for overflow. There will be a website soon. Stan Fox will be the SSAR representative to the local committee. Henry Mushinsky, Chairman of the Future Meeting Site Committee announced that the 2001 meeting will be held in Indianapolis at the DoubleTree Hotel from July 26–30.

Nominations for election to SSAR Board of Directors for 2000 were presented to the membership and accepted: President, David Green and Gregory Pregill; Director, Karen Lips and Rafael de Sá; Regional Director, Alvin Braswell and David Hardy, Sr.

—Respectfully submitted by Ellen J. Censky and John Matter.

1999 Resolutions

Resolution of Support for Partners in Amphibian and Reptile Conservation (PARC), a New Multi-Sector Conservation Initiative

WHEREAS, the mission of Partners in Amphibian and Reptile Conservation (PARC) is to conserve reptiles, amphibians, and their habitats as integral parts of our ecosystem and culture through proactive and coordinated public/private partnerships; and

WHEREAS, PARC and its members from both public and private sectors seek to form a coordinated and cooperative conservation partnership in this endeavor; and,

WHEREAS, the comprehensive national conservation strategy for reptiles and amphibians to be developed by PARC will incorporate issues in research, management, monitoring, policy/regulation/trade, and education outreach;

THEREFORE, be it
RESOLVED that the members of the Society for the Study of Amphibians and Reptiles express their support to the Partners in Amphibian and Reptile Conservation for their vision and commitment to the long-term conservation of reptiles, amphibians, and their habitats.

Adopted by the Society for the Study of Amphibians and Reptiles, 27 June 1999, at its Annual Business Meeting.

Honoring Outgoing SSAR Officers and Editors

WHEREAS, the following individuals have given freely of their time, skills, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year; and,

WHEREAS, they have therefore been instrumental in advancing the Society's goals and furthering its growth as an international scientific society; and,

WHEREAS, SSAR is dependent upon the generosity of these persons and those who have gone before them, and is greatly indebted to them for their fine efforts in its behalf;

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles offers its most sincere thanks to the following persons who have served in these capacities:

STEPHEN C. ADOLPH — Editorial Board, *Journal of Herpetology*
ROBIN M. ANDREWS — Nominating Committee
JAMES P. BOGART — Director, Local Committee Chair
JOSEPH T. COLLINS — Editor, Herpetological Circulars
DAVID CREWS — Editorial Board, *Journal of Herpetology*
C. KENNETH DODD, JR. — Conservation Committee
TODD ESQUE — Student Travel Awards
JEFF ETTLING — Zoo Liaison
LEE A. FITZGERALD — Associate Editor, *Herpetological Review*
TERRY E. GRAHAM — Meetings Committee
LOUIS J. GUILLETTE, JR. — Long Range Planning Committee
DAVID L. HARDY, SR. — Elector
JOHN B. IVERSON — Director
ELIZABETH A. JOHNSON — Advertising Manager, *Herpetological Review*
JULIAN C. LEE — Associate Editor, *Journal of Herpetology*, Grants-in-Herpetology Committee
KEN R. MARION — Kennedy Student Award
HENRY R. MUSHINSKY — Immediate Past President
GEORGE R. PISANI — Resolutions Committee
MARTIN J. ROSENBERG—Regional Societies Liaison
DOUGLAS E. RUBY — Associate Editor, *Journal of Herpetology*
BETH STOKES — Editorial Assistant, *Journal of Herpetology*
R. KATHRYN VAUGHAN — Section Editor, *Herpetological Review*
DAWN S. WILSON — Seibert Awards

BE IT FURTHER RESOLVED that the SSAR urges these persons not to disappear into the woodwork, but to be available as resources, with or without official titles, to guide those who follow in their service to the Society.

Adopted by the Society for the Study of Amphibians and Reptiles, 27 June 1999, at its Annual Business Meeting.

Seibert Award Winners for 1999 Announced

The eighth annual Seibert Awards were presented at the 42nd Annual Meeting of the SSAR at Penn State, 24–30 June 1999. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meetings, a single award was given in each of the following categories: Systematics, Ecology/Evolution, Physiology/Morphology, and Conservation. All four awardees received a check for US $200 and a book from Academic Press.

The Winners.—Conservation: Jeannine A. Ott, Department of Zoology, Auburn University (co-authors William Michener, Craig Guyer), "Home range and cohabitation patterns of a population: estimating gopher tortoise area requirements." Ecology/Evolution: Matthew A. Flowers, Department of Biology, Arizona State University, "Population variation in male color pattern and female preference in chuckwallas, *Sauromalus obesus*." Systematics: Rafe Brown, Department of Zoology, University of Texas, Austin (co-author Sheldon Guttman), "Phylogenetic systematics and historical biogeography of the *Rana signata* complex of Philippine and Bornean stream frogs." Physiology and Morphology: Jennifer Yeh, Department of Zoology, University of Texas at Austin (co-author David Cannatella), "The ontogeny of skull ossification in pipoid frogs."

Honorable Mention.—Systematics: Christoffer R. Feldman, Department of Biology, San Francisco State University (co-author Greg Spicer), "Comparative phylogeography of three squamate reptiles in California: *Contia tenuis, Diadophis punctatus* and *Elgaria multicarinata*."

The judges were: Bill Lutterschmidt (University of Oklahoma), Steve Beaupre (University of Arkansas), Joe Mendelson (Utah State University), Paul Stone (University of Central Oklahoma), and Kelly McCoy, chair (Angelo State University).

SSAR Student Travel Awards Call for Applications

Awards of US $200 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author (or co-author, see below) of a paper or poster to be presented. An applicant must include in the application package: 1) a letter signed by his/her major advisor or department chair that

states: he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Student Travel Awards Committee are excluded from applying for a travel award.

APPLICATIONS MUST BE POSTMARKED BY 15 MAY 2000. Award recipients will be notified by 1 June 2000 and award checks will be disbursed at the meeting. Direct requests for information to: *Stephen C. Richter, Department of Biology, The University of Oklahoma, Norman, Oklahoma 73019-0235, USA. Tel: (405) 325-4821; fax: (405) 325-6202; e-mail: richter@ou.edu.*

SSAR Student Awards Fund-raiser: 1999 Results and Call For 2000 Donations

Thanks to the many generous donations from several individuals to the 1999 silent auction at Penn State, the SSAR Student Travel Awards Committee (SSAR STAC) awarded seven US $200 travel grants to the following individuals: Matthew Bealor, Jennifer Yeh, Marc Mazerolle, Stefan Kaminsky, Meredith Mahoney, Emily Taylor, and Alison Hamilton. The SSAR STAC wishes to thank all who donated items to the 1999 auction at Penn State: Kraig Adler, Breck Bartholomew, David Dennis, S. R. Goldberg, Jackie Grant, Victor Hutchison, Julian Lee, Ernie Liner, R. Ruibal, Alan Savitzky, Norm Scott, and SSAR. The fifth annual Frameable Art Silent Auction raised over $1460 for future student travel awards. On behalf of the SSAR, thanks to all who helped, including Kristen Hickey and the Penn State meeting organizers. Special thanks for a job well done to the SSAR STAC Chairman, Lance McBrayer.

The SSAR STAC announces the Sixth Annual Frameable Art Silent Auction to be held at the 2000 SSAR meeting at La Paz. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please contact: *Stephen C. Richter, Department of Biology, The University of Oklahoma, Norman, Oklahoma 73019-0235, USA. Tel: (405) 325-4821; fax: (405) 325-6202; e-mail: richter@ou.edu.*

Notice to La Paz 2000 Meeting Attendees

Due to customs regulations involving the transportation of merchandise from outside of México, it may be difficult to obtain many of the usual SSAR auction items from vendors and publishers. Therefore, the Society is requesting that meeting attendees consider bringing auction items with them as gifts to the Society.

Grants-in-Herpetology Donations Sought

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible (for U.S. residents) contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

New Category for Grants-in-Herpetology Program

SSAR's Grants-in-Herpetology program has a new look for 2000. Thanks to a generous donation from long-time SSAR supporters Itzchak and Carolyn Gilboa, a new category has been added: Bibliographic Research. Proposals must address a major need to consult library holdings or other information resources in the context of herpetological research. Graduate students and other prospective applicants are encouraged to consult the detailed guidelines published in *Herpetological Review* 30(3):143.

NEWSNOTES

Reptile Database

Since last profiled in *HR* 27(4):174–175, the EMBL Reptile Database, developed and maintained by Peter Uetz, has grown, now containing taxonomic information (synonyms and distribution) for nearly all ca. 7900 living species of reptiles (exclusive of birds). There are links to photos for more than 1000 species.

www.embl-heidelberg.de/~uetz/LivingReptiles.html

Ashton Biodiversity Institute

The Ashton Biodiversity Research & Preservation Institute is a non profit organization which was incorporated in September, 1999. It is the organization which operates the conservation research and education programs on Finca de la Tortuga Biological Reserve, located on the Brooksville Ridge, 15 miles west of Gainesville, Florida, USA. The Institute is devoted to promote, support, and provide opportunities for research and management on biodiversity. In particular, it will contribute to the development of knowledge in conservation biology on endangered species and in sustainable use of natural resources. Along with research the Institute has at its core, the education and training of students of all ages from school students to graduate students and professionals on wildlife preservation and management. A special emphasis is given to reptiles and amphibians. The Board of Directors include herpetologists and ecologists representing different expertise: Patricia. S. Ashton and Ray E. Ashton, Jr. (Ashton, Ashton and Associates, Florida); Dave Collins (Tennessee Aquarium, Chattanooga, Tennessee); Elliott Jacobson (College of Veterinary Medicine, University of Florida); Henry R. Mushinsky (Department of Biology, University of South Florida): Peter C. H. Pritchard (Chelonian Research Institute, Florida). Its research director, Dr. Ghislaine Guyot from Lyon (France) has studied ecology and conservation biology of tortoises *Testudo hermanni* in France and rare side-necked turtles *Pseudemydura umbrina* and *Chelodina oblonga* in western Australia. She is here on a post doctoral position jointly sponsored by the Institute and the University of South Florida. In its first year, the Institute and the Preserve have hosted a number of intern and graduate students. A great deal of effort has been put to developing infrastructure (lab/library, living quarters, and baseline data gathering

and monitoring of the flora and fauna of the upland habitat). Two major projects which are on-going include a long term study on relocation and behavior of gopher tortoises, and the development of long term management strategies for maintaining highly endangered species of savannah dwelling tortoises. Currently this cooperative study includes the use of the Indian star tortoise, *Geochelone elegans* and the radiated tortoise, *Geochelone radiata* to develop management protocols. To obtain further information about the involvement with the Institute, graduate studies, internships and cooperative research possibilities, contact: *Ghislaine Guyot, Research Director, Ashton Biodiversity Research & Preservation Institute, PMB 331, 5745 SW 75th St., Gainesville, Florida 32608, USA; e-mail: GhGuyot@aol.com; Tel. 352-495-7449; Fax 352-495-7433.*

New Curator at MCZ

Dr. James Hanken has joined Harvard University as Curator in Herpetology at the Museum of Comparative Zoology and Professor in the Department of Organismic and Evolutionary Biology. All loan requests should be submitted in writing to Dr. James Hanken, Dept. of Herpetology, Museum of Comparative Zoology, 26 Oxford Street, Cambridge, Massachusetts 02138, USA. Collection-related questions and other materials (e.g., reprints) should be sent to José P. Rosado, Collections Manager (617-495-2496, voice; 495-5667, fax; jrosado@oeb.harvard.edu, e-mail).

The herpetology department encourages use of its research collections, which currently number more than 320,000 specimens. Limited funds for travel are available from the Ernst Mayr Grants to utilize the collections for systematic studies. Applications are reviewed semiannually, following submission deadlines of 15 September and 15 April. Awards are announced within two months after these dates. Correspondence related to these awards should be addressed to the Director of the Museum, Dr. James McCarthy.

Dr. Hanken's interests include evolutionary biology, morphology, development, and systematics. His research focuses on vertebrates, especially amphibians, but otherwise encompasses a broad range of organisms and problems. These include the morphological and developmental correlates and consequences of alternative reproductive modes, such as direct development; life history evolution; mechanisms of cranial pattern formation during embryonic and metamorphic development; and taxonomy and systematics of neotropical salamanders. Interested students should contact the OEB Graduate Program for further information regarding opportunities for advanced study <http://www.oeb.harvard.edu/GradProg/index.html>.

Information Sought on Argentine Lizards

The Wildlife Fauna and Flora National Agency of Argentina is re-evaluating the conservation status of amphibians and reptiles of Argentina. One of the criteria used for the evaluation concerns the commercialization of species—for the pet trade, zoo exhibits, food, or skin.

As lizard group coordinator, I am gathering information about Argentinean lizard commercialization in developed countries. We were surprised to learn that *Phymaturus patagonicus*, a rare and little known species (Chiszar et al. 1999. Herpetol. Rev. 30:98), is present in the U.S. pet trade. Like other *Phymaturus* species, it has a restricted geographical distribution.

A principal goal is to establish rules to control commercial activities with species vulnerable to extinction. If you have information about the commercialization of Argentinean species of the genera listed below, in United States, Europe, Japan or elsewhere, please send all the information available (species, origin, date, pet catalogue, etc.) to: Dr. Luciano Javier Avila, CRILAR-CONICET, Mendoza y Entre Ríos s/n, 5301 - Anillaco (La Rioja), Argentina; tel. 54 (0) 3827- 494251 Interno 113; fax 54 (0) 3827-494231; e-mail: lavila@crilar.com.ar.

International Society for the History and Bibliography of Herpetology

The International Society for the History and Bibliography of Herpetology was founded in 1998 in Guelph, Canada. The profound interest among many professional and amateur herpetologists in the history of their science or hobby was demonstrated in recent international herpetological meetings. The founders' conception was to launch a society that can provide a forum for herpetologists, bibliophiles, and historians of biology to meet and share their common interests. The initial founding group consisted of twelve persons. A constitution was laid down and an executive committee was elected. The Society is a not-for-profit organization.

Thus, the aims of the Society are to bring together individuals who have a serious interest in the history as well as the bibliography of herpetology and to support the spread of knowledge of these topics among members and the general public. Opportunities are created for the members to meet other people with the same interest and to extend and cultivate their acquaintances.

The Society will achieve its aims by organizing formal meetings with lectures, discussions, and other similar activities. These meetings will normally be held in connection with other herpetological meetings, such as congresses with international participation. Activities that include visits to private and public libraries, museums, research stations, antiquarian bookshops, etc., will be other means of assembly. The founders also feel that a dedicated channel for publishing papers in the disciplines is lacking. A printed bulletin with brief articles, essays, bibliographies, and news of people and events in our field will therefore be a central pillar of the Society. This will, as demands arise, be supplemented by a less formal newsletter that will be distributed either as a leaflet or e-mail.

The executive committee of five people is representing academic professionals, students, and amateurs from Canada, Sweden, and USA. The first bulletin was published in May 1999. Meetings were held in Pennsylvania, USA later in the summer. Members as a group were invited to an exclusive presentation of the library of the Academy of Natural Sciences in Philadelphia. The Academy is the oldest extant natural history museum in the United States and its exceptional book and journal holdings in herpetology were displayed.

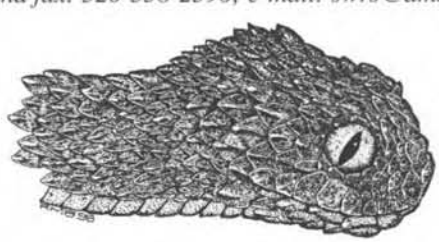
Elected officers for 1999–2000 are: Prof. Kraig Adler (Secretary/Treasurer, USA), Prof. Aaron Bauer (Meeting Organizer, USA), Ronald Javitch (Vice Chairperson, Canada), Ralph Tramontano (Editor, Sweden), and Richard Wahlgren (Chairperson, Sweden). The next meeting is planned for La Paz, Baja California, México in June 2000.

Membership fee for two years (2000–2001) is US $30 (student $10) or life $300. Anyone interested in more information about the Society is invited to visit our web site: www. teorekol.lu.se/~rana/ISHBH, and contact us from there or write to: *International Society for the History and Bibliography of Herpetology, Box 2123, SE-220 02 LUND, Sweden.*

Southwestern Research Station Positions And Grants For 2000

VOLUNTEERS—Approximately 30 volunteer positions are open in 2000 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.



Volunteers are needed between March 14 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. Application due date: February 15, 2000. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reservations, answering phones, greeting guests, supervising volunteers, etc. Begin mid-March 2000 through September 2000. Five-day week; salary $235/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

Atheris squamiger. Illustration by R. Michael Burger.

MEETINGS

Meetings Calendar

27–29 January 2000—Annual Conference of the Western Section of The Wildlife Society. Riverside Convention Center, Riverside, California, USA. Session on "Ecology and Conservation of Amphibians and Reptiles" included. Information and registration available via the society's website at: www.tws-west.org.

1 April 2000—All Florida Herpetology Conference, Florida Museum of Natural History, Gainesville, Florida. For more information, contact Max Nickerson, Florida Museum of Natural History, University of Florida, Gainesville, Florida, 32611 USA (e-mail: maxn@flmnh.ufl.edu).

14–20 June 2000—43rd Annual Meeting, Society for the Study of Amphibians, together with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists, Universidad Autónoma de Baja California Sur, La Paz, BCS, México. *(Refer to meeting announcement on page 193 of this issue).*

11–15 July 2000—Sixth Biennial Joint Meeting of Portuguese and Spanish Herpetologists and the Tenth Biennial Congress of the Spanish Herpetological Association, Valencia, Spain. For more information contact: VI Congreso Luso-Espanol, X Congreso Espanol de Herpetologia, Departamento de Biologia Animal, Facultad de Ciencias Biologicas, Universidad de Valencia, 46100 - Burjasot, Valencia (Spain). E-mail: herp2000@uv.es. Web site: http://bioweb.uv.es/zoologia/AHE.

16–20 July 2000—Fourth Asiatic Herpetological Conference, Chengdu Institute of Biology, Chinese Academy of Sciences, Chengdu, China. For more information contact: Dr. Theodore J. Papenfuss, Museum of Vertebrate Zoology, Berkeley, California 94720-3160, USA; tel. (510) 642-3567; fax: (510) 643-8238; e-mail: asiaherp@uclink4.berkeley.edu.

LEGISLATION & CONSERVATION

Utila Iguana Conservation

The Utila Iguana (*Ctenosaura bakeri*) is an island endemic now restricted to Utila Island (41 km^2) in Caribbean Sea on the Honduras coastline. This large iguana is threatened with extinction. The "Conservation Project of the Utila Iguana" has been developed to address various threats to extinction. The Project is under the joint sponsorship of the Frankfurt Zoological Society and the Senckenberg Nature Research Society. Project activities include: a broad education and information program for the local community; support a ban on hunting of the species through presence of game wardens and conservations on a nature reserve; research on the species' biology; a survey of the fauna and flora of Utila; creation and maintenance of a reserve; and the reproduction of Utila iguanas in a scientifically run breeding program.

Volunteers are needed. Undergraduate and graduate students in biology will gain experience in the conservation of species and field experience in the tropics. However, participants need not be formally trained in biology, but simply have a desire to be actively engaged in a species preservation project. Housing is available at

the IGUANA Research and Breeding Station for volunteers willing to commit themselves to 2–3 months of work.

For additional information, please contact the Project Director: Dr. Gunther Köhler, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt; e-mail: gkoehler@sng.uni-frankfurt.de or visit the Project Web site at: http://senckenberg.uni-frankfurt.de/fis/herp_ut_e.htm

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Anne Maglia or Christopher Sheil; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.herplit.com/contents

Larval and Metamorphic Skeletal Development of *Pyxicephalus adspersus*

Haas studied the development and ontogenetic change of *Pyxicephalus adspersus* (the African Bull Frog) raised in the laboratory at 29°C. Haas reports the development of this species being complete in 17 days from hatching, and metamorphosis taking only five days. He also states that the skeletal differentiation reached at the end of metamorphosis is similar to other species of frogs, despite the relatively rapid phase of development. No shift of cranial bone formation was reported after metamorphosis, and the majority of species compared to *P. adspersus* in this study were found to be particularly similar in the sequence of formation of elements of the postcranial skeleton; however, clear differences were found among species in the timing of these elements relative to the larval growth trajectories, absolute time, and certain developmental markers. Comparisons among taxa show that newly metamorphosed *P. adspersus* possess strong jaws with fang-like teeth, and a prominent squamosal-maxilla contact (likely enabling this frog to catch and swallow vigorous prey).

Haas, A. 1999. Larval and metamorphic skeletal development in the fast-developing frog *Pyxicephalus adspersus* (Anura, Ranidae). Zoomorphology 119:23–35.

Utilizing Characters of Isozymes in Systematics

Buth and Murphy summarize several classes of isozyme characters that can be of value in systematic studies. Of these classes, some of the more robust are recognized. The authors also state that in any study isozyme characters should be evaluated in terms of their advantages and limitations. A discussion of the taxonomic level of utility of isozymes is also included.

Buth, D. G., and R. W. Murphy. 1999. The use of isozyme characters in systematic studies. Biochemical Systematics and Ecology 27(1999):117–129.

Gene Expression in the Desert Tortoise, *Gopherus agassizi*

Optimal electrophoretic conditions for allozyme and isozyme studies were identified by examining the products of 73 enzyme loci with eight different buffer systems, for studies of *Gopherus agassizi*. Levels of enzyme activity were reported for extracts from blood, brain, eye, gonad, heart, kidney, liver, muscle, and stomach. The authors state that the systematic utility of these isozyme characters lies in the tissue distribution of some gene products, as well as the number of genes that control some enzyme systems.

Salamander Pheromone Isolated

In plethodontid salamanders, pheromones are used by males during courtship to induce copulation. Despite the fact that the behavioral effects of pheromones are well documented, few vertebrate pheromones have been isolated. Rollman and colleagues performed biochemical analyses on plethodontid courtship pheromones and identified a single protein, termed plethodontid receptivity factor (PRF), for which they also determined the DNA sequence. They tested the effects of PRF on female receptivity by applying the protein to females' nares and allowing them to interact with males whose natural pheromones had been removed. They found that 9/11 of the females responded positively to the pheromones. They suggest that because this pheromone changes the receptivity of females that are not ovulating, it may serve as a model system to study receptivity independent of ovulation.

Taxonomic Status of the Black Turtle

For over a century, the Black Turtle, *Chelonia agassizii*, has been recognized as a distinct species. However, there has been much debate about the validity of this taxon. Karl and Bowen conducted an analysis of sequences from three nuclear DNA loci of 11 indi-

viduals representing *C. agassizii* and the Green Sea Turtle (*C. mydas*), which is regarded by some workers as conspecific. Based on their results, they conclude that the variation between the *agassizii* and *mydas* is no greater than variation within the latter species as a whole, and therefore, these taxa should be synonymized. They point out, however, that recognition of the Black Turtle as distinct is, in part, based on conservation concerns. They conclude that rather than recognizing an invalid species, conservation efforts should target the Black Turtle as a distinct evolutionary unit, termed a Geopolitical Management Unit, within the species *C. mydas*.

Feeding Systems of Agamids

Many ecological studies have examined the interaction between morphology and ecology; however, few of these have been conducted on lizard feeding mechanics. The authors examined the anatomy and function of the feeding apparatus in lizards with different feeding strategies—the insectivorous *Plocederma stellio* and herbivorous species of *Uromastyx*. They found that the skulls of the herbivorous lizards are adapted for strong, forceful biting and are thermally dependent, whereas those of the insectivorous lizard are made to be fast and forceful during static biting. They conclude that the mechanics and morphologies examined are tightly linked to the lifestyles of these animals.

OBITUARIES

Sylvana Silvi Cei
1920–1998

Sylvana Cei, wife of long-time SSAR member José Miguel Cei, died suddenly on 21 February 1998. Together with her husband, Sylvana participated in numerous expeditions in search of amphibians and reptiles, traveling some 350,000 km in 25 years of field work in Patagonia, Peruvian Amazonia, Chaco, the Andean belt, Angola, and Namibia. One of her discoveries, the iguanian *Liolaemus silvanae*, endemic to an isolated mesa in Argentina, is named in her honor. Born near Pisa, Italy, on 4 November 1920, Sylvana was educated in Florence in the fine arts, mainly drawing and painting, and her exceptional aquarelles have long graced José's books and papers. She was also responsible for reorganizing the herpetological collections of the museum in Turin. Her death is a loss to our field, and we will miss her generous contributions to herpetology, her outstanding artistry, and her passion for natural history.

In Remembrance of Sherman A. Minton, Jr.
1919–1999

H. BERNARD BECHTEL

Valdosta, Georgia 31602, USA

Madge and Sherman Minton. Photograph courtesy of H. B. Bechtel.

I met Sherman Minton in 1955 in west Texas where, with Madge and his three young daughters, he was living in a simple cabin just north of Big Bend National Park. On leave from IU Medical School, he was researching ectoparasites of reptiles. I am an amateur herpetologist and was with a group hunting reptiles in the area. I must have been the only herpetologist, amateur or professional, who did not know of him, because he had already attained a position of prominence in the field of herpetology. I certainly did not know that this would be the start of a friendship, but it was.

A result of his stay in Texas was publication of the outstanding local faunal study, "Observations on Amphibians and Reptiles of the Big Bend Region of Texas." This paper contained the first published mention of the all-female populations of *Cnemidophorus* and also the first report of the extreme toxicity of the venom of *Crotalus scutulatus*, documented by his own toxicity studies on mice.

While in Texas, he also described a new snake, *Tantilla cucullata*, which subsequently has been reduced to a subspecies of *rubra*.

Sherm was born in New Albany, Indiana, and attended public schools. His father was a United States Senator from Indiana, and subsequently was appointed to the United States Supreme Court by President Harry Truman. From an early age, Sherm was fascinated with insects and natural history, but his life was transformed when he discovered Raymond Ditmars' "The Reptiles of North America." He had correspondence with Ditmars concerning a scarlet snake that he collected near New Albany in 1935, the first recorded Indiana specimen.

He earned a bachelor's degree in zoology from Indiana University in 1939, and graduated from IU Medical School in 1942 into a world consumed by war. Enlisting in the navy, he served as a Medical Officer in the Pacific Theatre of Operations from 1943 to 1946, both ashore and afloat.

While a student at Indiana University in 1937, Sherm met Madge Rutherford. They were engaged, but postponed marriage when the Civilian Pilot Training Program enabled Madge to realize her dream of flying. She then was accepted by the Women Airforce Service Pilots (WASPS). The WASPS flew military planes from point of manufacture, and handed them over to regular military pilots. In this capacity WASP pilots flew all of the military aircraft of the time. In 1943, between two flight assignments and just before Sherm reported for duty aboard the destroyer USS Brooks, they were married. The war ended for the USS Brooks when it was attacked by a Japanese kamakaze, too late in the war to be repaired and return to action.

From the beginning, Sherm and Madge collaborated as a team, with Madge assisting in the field and laboratory, and with writing and research on their books. It is really not possible to understand Sherm, or talk about him, except in association with Madge. She permitted Sherm to be completely absorbed in his work, while maintaining her own active role in the retired WASP association.

Upon discharge, he did graduate study in Microbiology and Herpetology at the University of Michigan, and joined the faculty of Indiana University School of Medicine. Sherm chose an academic career without the enthusiastic support of his father, who was "more practical" and felt that a medical degree would be better used practicing medicine. From 1948 until his retirement in 1984, he was a member of the Department of Microbiology and Immunology at the IU Medical School, and was Professor Emeritus at the time of his death. From 1957 on, he was a research associate in the Department of Herpetology at the American Museum of Natural History.

Sherm's position as a professor at the IU School of Medicine enabled him to pursue his real love, herpetology, which he did with single-mindedness for the remainder of his life. In 1958 he accepted an offer to be a visiting Professor of Microbiology at Jinnah Postgraduate Medical Centre in Karachi, Pakistan, staying until 1962. Closing their home in Indianapolis and moving the entire family to Pakistan was a tremendous upheaval, but it was an opportunity he could not pass up. His primary duties in Pakistan were teaching and providing short-term medical care for employees, students, and staff of the institute, allowing him to pursue herpetology, which he did with his customary vigor. He did limited work on snake and scorpion venoms, made clinical observations on snakebite cases, and carried out extensive field studies on the herpetofauna of Pakistan, resulting in the publication of "A Contribution to the Herpetology of West Pakistan," a crucial regional work and a natural history classic. While the Mintons were in Pakistan, I received a steady stream of cardboard boxes in the mail, containing lizards and snakes that I only vaguely knew existed. I must have been the first person in America to possess a fat-tailed gecko or a Turkestan plate-tailed gecko, neither of which I had ever seen, even in zoos.

Sherm's activities included extensive travel. In 1965 he visited parts of Iran and Pakistan as a member of the American Museum of Natural History. He was a delegate to conferences on venomous animals and venoms at Instituto Butantan, São Paulo, Brazil, in 1966 and 1981. In the winter of 1972–1973 he was a member of a Scripps Institute of Oceanography expedition to the Timor Sea and Australia to study the biology of seasnakes and other dangerous marine animals. He was a member of a second expedition to the Philippines in the fall of 1975, and a third to the Chesterfield Islands and Great Barrier Reef in the summer of 1981. In 1976 he was a delegate to the U.S.-Republic of China Binational Seminar on Protein Chemistry and Snake Venoms. For six months in 1980 he was visiting professor in the Department of Zoology, University of New England, Arimdale, Australia. He was delegate to WHO-sponsored meetings on venoms in Switzerland in 1979 and Japan in 1980. In 1983 he returned to Pakistan for the 25th anniversary of the Jinnah Postgraduate Medical Centre. He made professional visits to England and Yugoslavia in 1985, Mexico in 1987, and the People's Republic of China in 1991. Madge accompanied him on all of these trips.

Sherm's most recent research activity involved envenomation by non-native snakes in the U.S., distribution and natural history of Indiana reptiles and amphibians, the decline of amphibian populations in Indiana, and the bites and venoms of colubrid snakes. When he published an article on this last subject in a magazine for general readership, we often discussed how this might be misinterpreted by the public, who have long been reassured that gartersnakes are harmless.

He was author or coauthor of about 150 technical papers and monographs as well as articles in textbooks, encyclopedias, and nontechnical publications, and editorials and book reviews. He and Madge coauthored two popular books: "Giant Reptiles" and "Venomous Reptiles." "Venomous Reptiles" was extremely well-received, crammed with facts not readily available elsewhere, and is often quoted in peer-reviewed articles. He published "Venom Diseases," a source book for physicians and those with potential contact with venomous animals and their venoms, and was co-author of "Handbook to Middle East Amphibians and Reptiles." He was chairman of the committee that produced the U.S. Navy's official publication on poisonous snakes of the world and treatment of their bites, and edited a book on snake venoms and envenomation.

Sherm was consultant on snakebite and other envenomations for three major zoos and several poison information centers. In this position he shared by phone his knowledge of snakebite treatment with physicians struggling in emergency rooms with snake bites about which they had little knowledge.

His research, publications, and consultations on toxinology have been diverse and influential. A 1954 paper by Sherm indicated that Wyeth Laboratories' original antivenin was not effective against the venoms of major North American pit viper species. It is likely that this research led to significant changes by Wyeth, and the new formulation has remained essentially unchanged since 1955. His broad interests included toxicity and immunological relationships of snake venoms.

Sherm was a member of many scientific societies, and a leader in most of them: American Society of Ichthylologists and Herpetologists (former member of Board of Governors); American Society of Tropical Medicine and Hygiene; The Herpetologists' League; Indiana Academy of Science (Fellow, 1967, Speaker Of The Year, 1982); International Society on Toxinology (President 1966–1968, recipient of Redi Award, 1985); New York Academy of Sciences; Society for the Study of Amphibians and Reptiles (former member

of Board of Directors, President, 1985–86); and Wilderness Medical Society. He belonged to Sigma XI and the medical honorary society, Alpha Omega Alpha, and in 1996 Indiana's governor declared Sherm a "Sagamore of the Wabash," a singular honor for outstanding Hoosiers.

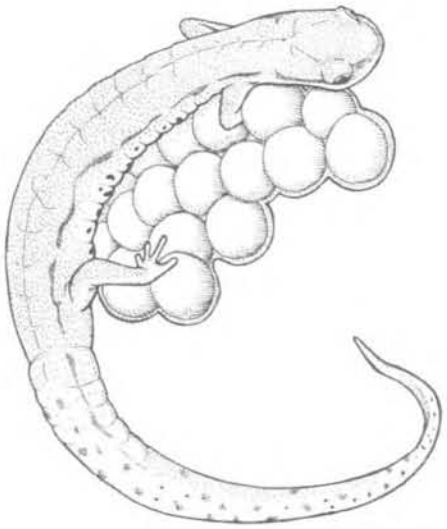
This list does not even begin to convey what Sherm meant to these organizations. With diverse interests and ongoing research, he was on the program too many times to list. Between sessions and at mixers, a crowd could always be found around him. In addition to being well informed in all aspects of herpetology, he was more widely traveled than most, and above all was the authority on venomous snakes and their venoms. Almost all herpetologists, no matter what field they were working in, are interested in snakebite, even if only as potential victims. He also was a popular speaker for regional herpetological societies.

Sherm and Madge often shared Thanksgiving in Valdosta with us and our local friends, and we have spent much time in their home. They were great hosts, and remarkably comfortable to have as guests. In spite of the fact that we spent so much time together, I am embarrassed to confess that I was not aware of all of Sherm's accomplishments until I undertook this obituary. Our friendship was such that he rarely discussed in depth his many trips unless asked about them.

The two of us spent a lot of time tramping around in south Georgia and southern Indiana, resulting in some of my fondest memories. Despite the fact that he had collected exotic specimens everywhere he went, he never lost his enthusiasm for local "herps," and he was a thorough observer. He always carried with him in the car a box containing preserving materials, which Bette, my wife, referred to as the "black box." Road kills were generally preserved on the spot, and notes made before the facts faded. On our tramps together, he invariably carried a camera, photographing not only reptiles, but flowers and most living things. In spite of the fact that south Georgia is reputed to be the home of many rattlesnakes, we only once came upon one, and it passed up the opportunity to bite us. Sherm pulled over a piece of corrugated metal, revealing a neatly coiled eastern diamondback rattlesnake. As he was bending over to photograph it and I was holding the metal, the snake noted some light under the tin and dived for it before we could react, passing within inches of our legs, and we both were wearing low shoes.

Sherm was, above all, a modest and self-effacing man, without pretense. For budding herpetologists, he was easy to approach, unfailingly helpful and encouraging, even when corresponding with those he had never met. The Mintons' unpretentiousness extended to their life style. They drove battered little Toyotas for the most part. Their home was unremarkable from the outside, but "lived in." It was filled with mementos from their travels, a huge herpetological library, walls of slides, stacked manuscripts and book reviews in progress, a few favorite live specimens, and Madge's archival material from the retired WASP organization. Finally, the basement was crammed with thousands of preserved specimens, donated upon Sherm's death to the American Museum of Natural History.

It was not all herpetology. When the opportunity arose, Sherm and Madge were the first on the dance floor. They were worthy opponents at bridge. Their politics were to the left of ours, but Sherm and I mellowed somewhat. Madge, however, always had with her a stack of liberal periodicals for my reading benefit. The Mintons enjoyed scuba diving, which they did as long as they were physically able, always stopping at Valdosta on the way to south Florida. Bette considered Sherm "easy to cook for!" His martinis conformed to the original recipe: no vodka substituted for gin; no onion substituted for the olive. At motel pools Sherm dived in without testing the water. He and Madge swam regularly, and on his 82nd birthday he swam a mile, but according to Madge, "very slowly."



A few weeks before he became ill, we had made arrangements to meet the Mintons in North Carolina for a few days' relaxation and salamander hunting, the two being synonymous. On March 15 Sherm had a seizure, and found out that he had carcinoma of the lung with brain metastases. He was in the field in southern Indiana the day before.

Upon learning of his illness, we drove to Indianapolis for a final visit. Sherm was not in pain but could not stand or walk, was able to talk only in a whisper. We did manage to lift him into a car and drive to Brown County, where he spent a few minutes looking at a small pond well-known as a breeding site for spotted salamanders, and released some captive native snakes that he had. I think that our friendship was so great because we were both physicians, of the same generation, and our wives got along so well. The last night of the visit, Bette and I helped Madge put Sherm to bed, the last time we saw him alive.

Sherm spent many hours of his last years in the field and at his word processor revising "Reptiles and Amphibians of Indiana." He was fond of Indiana and knew its herpetofauna as no other person does, and no other herpetologist probably ever will, because the Indiana he knew is disappearing fast. A great disappointment to him and all of us who knew him, was that he never lived to see the revised edition published.

Other herpetologists are also medical doctors, but no other physician-herpetologist has matched the herpetological accomplishments of Sherman A. Minton. Nor is there any physician-herpetologist working on snakebite treatment and basic research in snake venoms with a similar knowledge and publication record in herpetology. Being a herpetologist enhanced Sherm's toxinological work with a unique integration of medicine, toxinology, and herpetology. By any standard, Sherman Minton will be remembered as one of the leading herpetologists of this century. This is all the more remarkable considering his career as a professor in a major medical school.

Sherman Minton died June 15, 1999 at a hospice, with Madge at his side. He is survived by Madge; daughters Brooks Cervantes, April Kieser, and Holly Minton; sister Marriane Callanan; brother John Evans Minton; and two grandchildren.

Monthly Distributions of Size Classes and Reproductive Status in *Cnemidophorus tesselatus* (Sauria: Teiidae) from Southeastern Colorado

HARRY L. TAYLOR
Department of Biology, Regis University, Denver, Colorado 80221, USA

and

JAMES E. CORDES
Division of Sciences, Louisiana State University, Eunice, Louisiana 70535, USA
e-mail: jcordes@lsueccgt.lsue.edu

It is known that *Cnemidophorus tesselatus* (as redescribed by Walker et al. 1997) originated from hybridization between *C. tigris marmoratus* and *C. gularis septemvittatus* (Dessauer and Cole 1989; Neaves 1969; Parker and Selander 1976). This species exhibits remarkable morphological and ecological variation despite its parthenogenetic mode of reproduction and clonal pattern of inheritance (Dessauer and Cole 1986). *Cnemidophorus tesselatus* is, therefore, of considerable interest for what it can reveal about evolution in a parthenogenetic species.

Variation in *C. tesselatus* is evident as fundamental color pattern classes, designated as C, D, and E by Zweifel (1965) and as C, Colorado D, New Mexico D, and E by Taylor et al. (1996) and Walker et al. (1997). Parker and Selander (1976) and Parker et al. (1989) presented evidence that genetic variation within certain color pattern classes could have originated from different hybridizations or fertilizations between the two progenitor species. However, three lines of evidence suggest that color pattern classes were derived subsequent to the origin of *C. tesselatus*. First, histocompatibility between pattern classes C and E, as revealed by skin transplants (Maslin 1967), indicates that these populations originated from the same fertilization. Second, sympatric populations of pattern classes C and New Mexico D are identical at 30+ loci (Dessauer and Cole 1986), supporting the probability of a monophyletic origin. Third, mtDNA evidence has identified *C. tigris marmoratus* as the maternal progenitor of all color pattern classes, thus eliminating reciprocal crosses with *C. gularis septemvittatus* as an explanation for the color pattern differences (Densmore et al. 1989; Dessauer et al. 1996).

Although the genetic basis of color pattern classes in *C. tesselatus* has not been determined, recognition of color pattern differences was essential for correcting misconceptions regarding the community structure of sympatric color pattern classes of *C. tesselatus* (2n) and *C. neotesselatus* (3n) in the vicinity of Higbee, Otero County, Colorado (Walker et al. 1995). As a grouping variable, color pattern class has also demonstrated its value in revealing ecological differences within *C. tesselatus*; i.e., between populations of pattern classes C and Colorado D from the Higbee area (Walker et al. 1997[1998]). The present study compares monthly frequency distributions of body size and reproductive activity in these same populations (Fig. 1). With the exception of condensed data for pattern class C from northwest Texas (Tinkle 1959), this information is lacking for all populations of *C. tesselatus*.

Methods and Materials.—Specimens were collected from sites separated maximally by approximately 11 km; specific information is provided in Appendix I. The snout-vent length (SVL) of each available specimen was measured to the nearest mm from tip of snout to the posterior margin of the preanal scales. Reproductive status of each individual was determined by dissection, using either vitellogenic ovarian follicles (≥ 3 mm in diameter) or oviductal eggs as indicators of sexual maturity. Monthly distributions of SVL were compared between color pattern classes using the Mann-Whitney U test.

Results and Discussion.—Although specimens collected in different years (Appendix I) were pooled to depict composite frequency distributions, variances for SVL were homogeneous (Levene's test) between pattern classes for both non-gravid ($F = 1.603$, $P = 0.21$) and gravid ($F = 0.028$, $P = 0.87$) groups. There were no significant differences between pattern class C and D in SVL distributions in either gravid females (June: Mann-Whitney $U = 134.5$, $P = 0.20$; July: $U = 8.0$, $P = 0.57$) or non-gravid individuals for three of four months (June: $U = 7.0$, $P = 0.24$; July: $U = 161.0$, $P = 0.37$; September: $U = 295.0$, $P = 0.38$). During August, however, SVL distributions differed significantly between pattern classes C and D ($U = 863.0$, $P = 0.001$), apparently due to a greater number of hatchlings in pattern class D (Figs. 2, 3). Our interpretation of the frequency distributions follows.

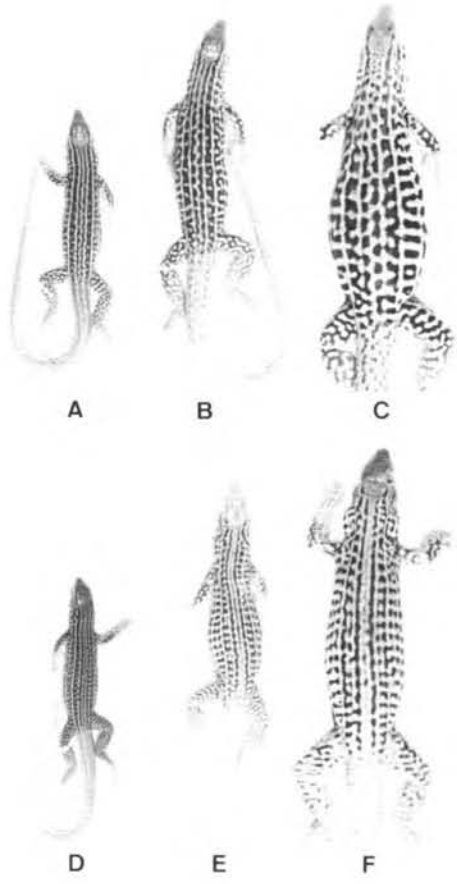

FIG. 1. Consistent ontogenetic color pattern differences between color pattern classes C and D of *Cnemidophorus tesselatus* from the vicinity of Higbee, Otero County, Colorado. Representative specimens are identified by UADZ numbers followed by their snout–vent length (SVL). TOP ROW—Pattern class C: A. 6343 (55 mm); B. 3187 (73 mm); C. 3184 (101 mm). BOTTOM ROW—Pattern class D: D. 6339 (48 mm); E. 3161 (71 mm); F. 4483 (98 mm).

September: Individuals 37–53 mm SVL likely represent a pooled cohort hatched between 11 August and the first week of September. Collecting records indicate that a majority of adults enter hibernation during this same time period, thus coincidentally reducing the overlap of activity between hatchlings and larger conspecifics.

June: Individuals emerge from hibernation in May, but activity is sporadic until June. Individuals hatched in the previous year are now 53–68 mm SVL; a second group is composed of reproductively mature individuals 78–105 mm SVL.

July: Individuals hatched in the previous year have grown to 67–78 mm SVL. A few individuals in the 92–105 mm size range are still ovipositing, but the absence of gravid individuals of both pattern classes in samples collected on 9 and 10 July indicate that reproduction is essentially over by the second week of July.

August: Hatchlings (32–47 mm SVL) are present. Most individuals hatched the previous year have now surpassed the minimum body size (approximately 78 mm SVL) at which reproductive maturity is achieved.

Gravid individuals of pattern classes C and D from the Higbee vicinity are similar in mean SVL and clutch size (Taylor et al. 1999). Reproduction in both pattern classes appears to begin in year three. This reproductive pattern is also apparently characteristic of pattern class C from northwestern Texas (Tinkle 1959) and pattern class C from Sumner Lake State Park in east-central New Mexico (Taylor et al. 1997). Any disadvantage accrued from delaying reproduction until the third year is evidently balanced by larger clutches made possible by larger body sizes attained from an additional year of somatic growth (Taylor et al. 1997).

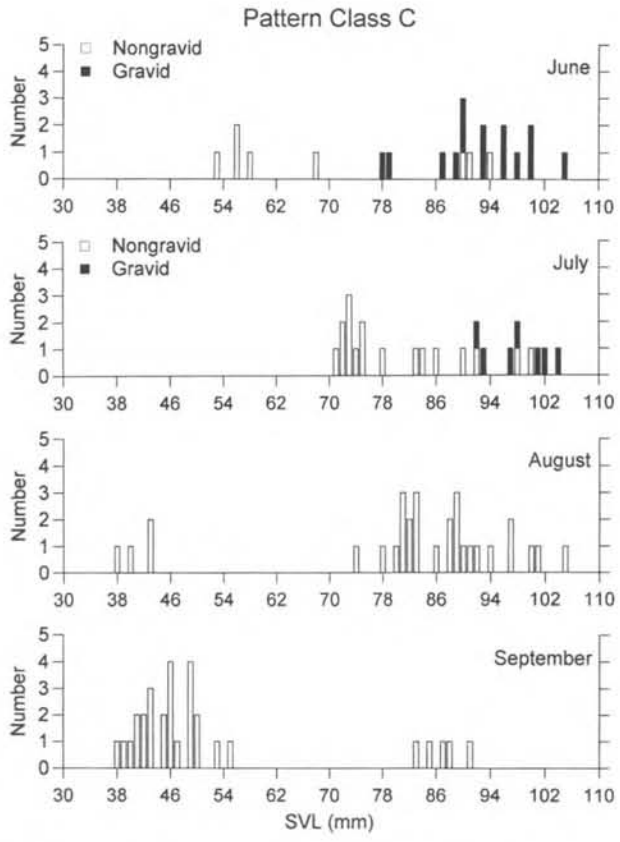

FIG. 2. Annual pattern of body sizes (SVL) and reproductive condition in pattern class C of *Cnemidophorus tesselatus* from the vicinity of Higbee, Otero County, Colorado.

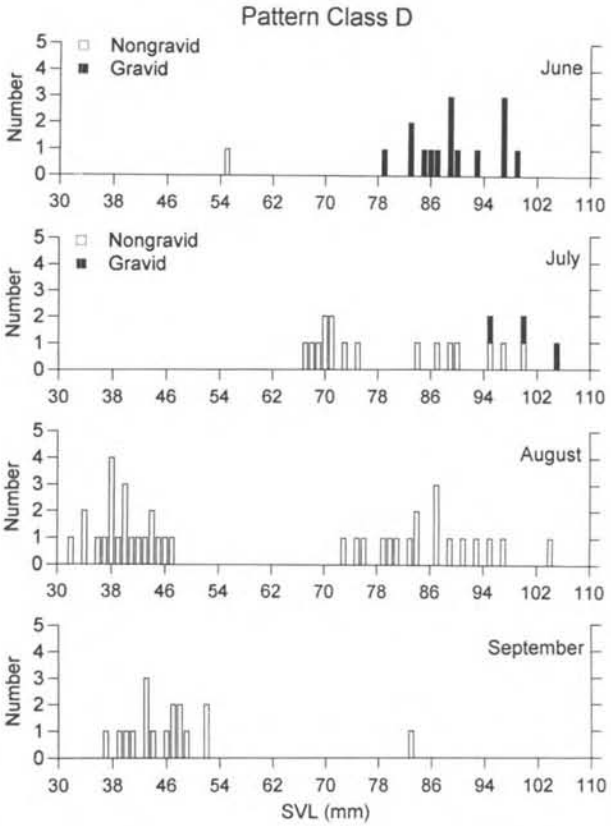

FIG. 3. Annual pattern of body sizes (SVL) and reproduction condition in pattern class D of *Cnemidophorus tesselatus* from the vicinity of Higbee, Otero County, Colorado.

We conclude that pattern classes C and Colorado D from southeastern Colorado have similar annual patterns of growth and reproductive activity despite certain morphological and ecological differences. Collecting records indicate that both pattern classes are active on suitable days from the middle of May through early October in southeastern Colorado. Pooled data were used to produce a population model (Figs. 2 and 3) from which it is possible to predict the monthly composition of populations of both pattern classes. Our most recent visits to the area (6 September 1998 [six juveniles collected] and 23 May 1999 [observations of three juveniles hatched in 1998 and three large adults]) fit the expectations predicted from the model.

Acknowledgments.—We are grateful to the Division of Wildlife, State of Colorado, for collecting permits. We thank S.–K. Wu, A. de Quiroz, and R. Humphrey, University of Colorado Museum, for accessioning samples, loans of specimens, and information concerning certain specimens in their care. Our appreciation is extended to K. K. Taylor and J. M. Walker, Jr. for field assistance, and we are indebted to B. E. Leuck, Centenary College, for information initially clarifying the distributions of color-pattern classes of *Cnemidophorus* in the Higbee vicinity.

The parthenogenetic whiptail lizard *Cnemidophorus neomexicanus* is known primarily from the vicinity of the Rio Grande Valley from Espanola, Rio Arriba Co., New Mexico south to near Candelaria, Presidio Co., Texas, and extending westward in southwestern New Mexico to west of Lordsburg, Hidalgo Co. (Fig. 1; Axtell 1966; Cole et al. 1988; Cordes et al. 1989; Degenhardt et al. 1996; Pough 1961; Wright 1971). An isolated population at Conchas Lake, San Miguel Co., New Mexico is possibly introduced (Leuck et al. 1981, but see Walker et al. 1992). Throughout its range *C. neomexicanus* occupies sandy, disturbed habitats such as flood plains (along the Rio Grande), sandy washes, and the edges of playas in closed basins (Cole et al. 1988; Cordes et al. 1989; Wright 1971; Wright and Lowe 1968), and is even common in weedy fields and vacant lots in and around cities and towns such as Albuquerque and El Paso (pers. observ.).

As this is not a taxonomic article, we will not review the extensive debate on the nomenclatural status of *C. neomexicanus* (see Smith et al. 1997 for a review). In anticipation of a ruling by the International Commission on Zoological Nomenclature to conserve the name *C. neomexicanus* (Smith et al. 1997), we continue to use it here.

FIG. 1. Approximate distribution of *Cnemidophorus neomexicanus*. Circle in NE New Mexico represents isolated population at Conchas Lake (Leuck et al. 1981), and circle in NE Arizona represents newly discovered population at Petrified Forest National Park. Map modified from Cole et al. (1988) and Wright (1971).

Here we report on a newly discovered population of *Cnemidophorus neomexicanus* at Petrified Forest National Park (PEFO), Apache Co., Arizona (USA). This constitutes the first record for the species in Arizona. In the course of herpetofaunal surveys being conducted in the park, numerous individuals of *C. neomexicanus*, of all age classes, were observed during the summer of 1998 along the flood plain of the Puerco River in section 9, Township 18 North, Range 24 East, Gila and Salt River Base Meridian, Apache Co., Arizona. A voucher specimen collected 13 August 1998 is deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM 144792). This specimen is also cross-catalogued with the National Park Service as PEFO 14756. The only other whiptail species occurring sympatrically with *C. neomexicaus* at this site, *C. velox*, is more abundant. Other lizard species observed at this site were *Sceloporus undulatus*, *S. graciosus*, and *Phrynosoma douglassii*. *Crotaphytus collaris* and *Uta stansburiana* were common in rocky areas nearby. The habitat is sandy flood plain with the shrubs *Chrysothamnus nauseosus*, *Atriplex canescens*, *Artemisia tridentata*, and *Forestiera neomexicana* dominant. Scattered large cottonwoods (*Populus* spp.) provide habitat in the form of downed limbs and leaf litter. Tamarisk (*Tamarix* spp.) is dense in areas, and *C. neomexicanus* appears to be less common in these stands. Overall the habitat is similar to that inhabited by conspecifics in the Rio Grande Valley.

As with the population at Conchas Lake in northeastern New Mexico (Leuck et al. 1981), this new population could have resulted from an introduction. Currently, a distance of ca. 240 km separates PEFO from the closest known populations near Laguna, Cibola (=Valencia) Co., New Mexico (Axtell 1966). While on the basis of biogeography and habitat *C. neomexicanus* could conceivably occur as far west as Grants, along the Rio San Jose (a tributary of the Rio Grande), it would still have to cross ca. 95 km of unsuitable habitat straddling the continental divide, until it could again reach apparently suitable habitat near Gallup (along the Puerco River, a major tributary of the Little Colorado River, that runs through PEFO). Introduction is suggested by several factors. One is the apparent disjunction of this population and the fact that both Interstate 40 and the Santa Fe railroad are major routes that connect the Rio Grande Valley and Albuquerque to PEFO. Both routes parallel the valleys of the Rio San Jose and Puerco River, where suitable riparian and urban habitats are common. Additionally, this new locality is immediately adjacent to the Puerco Ruins visitor site, one of the most visited areas at PEFO, and is only ca. 2 km east of the Adamana Station and Siding of the Santa Fe railroad. Skin grafting studies (in progress) will help to determine if this new population is identical to New Mexico populations of *C. neomexicanus*, and ongoing surveys will determine the extent of its distribution in Arizona.

The existence of an apparently healthy, reproducing population of *C. neomexicanus* at PEFO is significant. Histocompatibility, mitochondrial DNA, and protein electrophoresis studies suggest that *C. neomexicanus* is an extremely young species that has colonized its entire range in New Mexico and Texas in perhaps hundreds rather than thousands of years (Cuellar 1977; Densmore et al. 1989; Parker and Selander 1984). In New Mexico, *C. neomexicanus* has expanded its range at the expense of *C. inornatus*, especially where the habitat has been disturbed by humans and their livestock (Wright and Lowe 1968). Suitable disclimax habitats are extensive in the Little Colorado River basin of northeastern Arizona and northwestern New Mexico, and once established (as at PEFO), *C. neomexicanus* could rapidly colonize much of the watershed. We can only speculate on what effect *C. neomexicanus* may have on other species of *Cnemidophorus* (e.g., *C. velox, C. tigris, C. inornatus)* in the Little Colorado River basin.

Acknowledgments.—We thank Charles A. Drost and Erika M. Nowak of the Colorado Plateau Field Station (CPFS) for encouraging our lizard chasing and reviewing the manuscript; Mark DePoy, William Grether, Patricia Thompson, and the rest of the staff at Petrified Forest National Park for allowing us to survey and collect lizards; Andrew H. Price and James M. Walker for their helpful comments on the manuscript; and the CPFS GIS laboratory for producing the map.

Egg attendance is a widespread form of parental care in salamanders (Crump 1995), and it commonly co-occurs with egg suspension from overlying surfaces (Petranka 1998). This association between egg attendance and suspension implies that the latter is an important component of the reproductive strategy of many caudate amphibians, notably plethodontids (Petranka 1998). Brief descriptions of egg suspension among terrestrial salamanders indicates that it requires unconventional postures, is protracted over many hours, involves the synthesis and application of attachment substances, and entails precise egg placement and manipulation (Bishop 1941; Cupp 1991; Nobel and Richards 1932; Piersol 1914). Curiously, not all females within a species may suspend eggs (e.g., *Plethodon cinereus*; Bishop 1941; Wareing 1998), which leads to further questions of what factors influence clutch suspension within and across species.

The occurrence and complexity of egg suspension indicates the fundamental importance of this behavior, yet neither detailed descriptions of oviposition behavior nor experiments clarifying function have been reported. For this reason, we recorded details of oviposition during a broader study of maternal care by the red-backed salamander, *Plethodon cinereus* (Wareing 1998). Females typically lie on their backs and suspend a clutch of 3–14 eggs from a rock or log within an underground cavity during June and July in New York, and then the female attends the clutch for approximately 60 days until hatching (Bachmann 1964; Bishop 1941; Piersol 1914; Wareing 1998). To induce egg-laying for laboratory studies, we injected visibly gravid females in mid-June with an agonist of LH-RH (Verrell 1989; Wareing 1998); 21 of 29 injected females oviposited. Five females were observed during oviposition, all in the process of suspending a clutch. The behavior of one of these females was monitored during oviposition of an entire clutch on 19 June 1997 beginning at 1100 h. This sequence is described below because it accurately represents the shorter segments of oviposition behavior observed in the other four females.

Two days after injection, the "focal" female was in the process of laying her first egg. She had been isolated in a plastic chamber (30 cm x 15 cm x 12 cm) lined with a moist paper towel and a piece of rotting hemlock log used to simulate a natural nest cavity. Space was available for either suspension or substrate placement of the eggs, and the female was allowed to remain isolated with her eggs for the duration of brooding. The room was kept at 20°C in constant darkness, and observations were made under dim red light.

The female was found on her back under the log in a "sigmoid" posture with her two hind limbs contacting the log and only a portion of her tail and back supporting her body (Fig. 1). That the female was not suspended by her hind legs was suggested from observations on another captive female, whose log was lifted up when she was ovipositing. This female remained on the bottom of the chamber rigidly fixed on her back in the sigmoid position supported by her torso and tail. Had she been suspended by her hind limbs, she should have been displaced when we moved the log. Thus, the hind limbs of the focal female probably stabilized her position under the log while her back and tail push against the substrate to force the vent against the log.

When observations began, the focal female was motionless in a "resting" sigmoid posture with her head on the substrate and her forelimbs extending posteriorly and resting on the ventral surface of her body. A milky viscous substance seeped from her vent, and 3–4 eggs were clearly visible through the abdominal wall. She remained in this position for 10 min and then her body became more tensed, her head was raised off the substrate, and her forelimbs were held rigidly out from her body (Fig. 1). The first egg appeared suddenly at the vent, and in two seconds, the entire egg

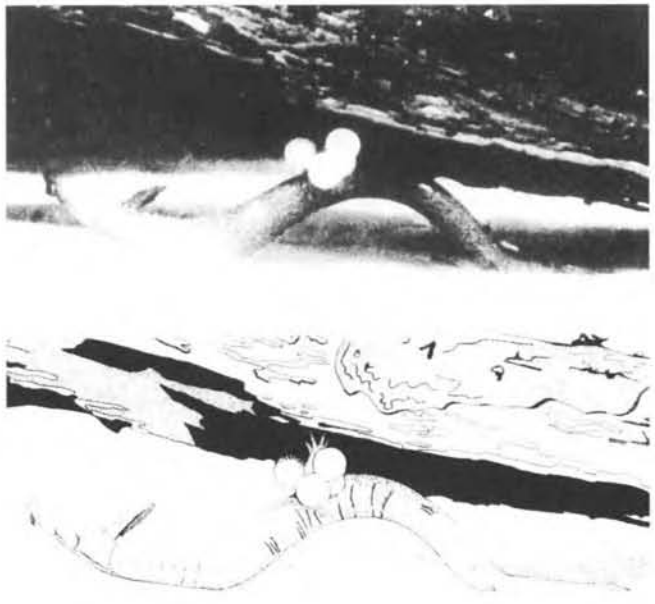

FIG. 1. Photograph and illustration of an ovipositing female *Plethodon cinereus* in an upside-down "sigmoid" position while suspending a clutch in a laboratory chamber. This female took 4.5 h to produce a clutch of 7 eggs and remained in the sigmoid over 6 h.

was deposited and adhered to the underside of the log. The female then returned to the "resting" sigmoid for 12 min until the beginning of the next oviposition sequence.

The remaining 6 eggs in the clutch were deposited in the following, more elaborate manner with about 45 min between eggs (18–65 min range). Each egg appeared only after numerous "contractions" had occurred. With each contraction, the female raised her head off the substrate, extended her forelimbs, and moved her forelimbs up and down either alternately or together for 10–30 sec. Then, she relaxed her head and forelimbs but otherwise remained in the sigmoid posture. An exact number of contractions was recorded for the second egg, which appeared following 13 contractions; there were intervals ranging from 5 sec to 12 min between contractions. It took the female 4.5 h between the appearance of the first and last eggs to complete oviposition of the clutch. Since she probably had initiated contractions before we began observations, and since she remained in the sigmoid posture for 105 min after ovipositing the last egg, the duration of the entire egg-laying process probably lasted for about 6.5 h.

The female righted herself and left the egg mass at 1715 h. At this point, the clutch resembled a suspended mound of eggs with three eggs in direct contact with the log. At 1730 h, the female returned and pushed and rubbed the eggs with her snout and chin, appearing to make contact with all surfaces of each egg in the clutch of 7 eggs. This nudging continued unabated for an hour, gradually became less vigorous over the next hour, and by 2100 h the female was quiescent under the clutch with the dorsal surface of her snout in contact with the clutch. As a result of the thorough nudging, the female rearranged and partially rotated the clutch into a grape-like cluster suspended by a single stalk leaving no eggs in contact with the log.

The eggs were solid whitish masses (no gelatinous outer membrane or layer evident) that adhered and/or were attached to each other. The milky secretion observed initially at the female's vent may form into the strands that are reported to hold the eggs together and merge to form the stalk (Piersol 1910, 1914).

These observations corroborate and extend the descriptions of oviposition for *P. cinereus* by Piersol (1910, 1914). In particular, the sustained upside-down arching posture, the cloacal placement and adherence of eggs on an overlying surface, and the prolonged maintenance of the oviposition posture well after the appearance of the last egg are identical to previous descriptions. The intensity and repetition of the contractions required for oviposition and the formation of the stalk by manipulations of the clutch after oviposition are new observations for caudate amphibians.

The occurrence and complexity of egg suspension implies that suspended eggs have some advantage over those on the substrate. Egg suspension may facilitate female protection of eggs against pathogens, predators or dehydration, which are functions given for egg attendance (Austin 1997; Crump 1995). We have no direct evidence of benefits to suspension, but tailed females in our laboratory studies cannibalized 100% of their non-suspended eggs compared to 50% of their suspended eggs (Wareing 1998). Because some female plethodontids improve egg survivorship by eating dead or dying eggs in their own clutches (e.g., *Desmognathus ochrophaeus*, Forester 1979), our laboratory observations may indicate greater viability in suspended eggs.

Another important implication of egg suspension is that females without tails may be particularly handicapped during oviposition. One handicap would be a reduction in the energy available for suspension and subsequent egg care. Maiorana (1977) reported less frequent reproduction among female *Batrachoseps* without tails, and she attributed this to the loss of stored energy in the tail. A second handicap would be the loss of the propping action of the tail, which our observations indicate would make suspension difficult. Bishop (1941) observed a "bobbed-tailed" *Hemidactylium scutatum* ovipositing, but the relative success of females with and without tails has not been evaluated. Salamanders lose tails in interactions with predators (Arnold 1982; Wake and Dresner 1967) and conspecifics (Jaeger 1981; Mathis 1991), and we speculate that one cost of losing a tail may be compromised egg suspension during oviposition. Clearly, egg suspension needs more critical examination as an important component of caudate reproduction.

Acknowledgments.—We are indebted to David Tuttle for photographic assistance, and to the Department of Biological Sciences of Binghamton University for financial support.

In the past, it was thought that the social behavior of snakes was limited to fighting and mating (Gillingham 1987). However, observations of aggregations of gravid females (Gillingham 1987; Gregory et al. 1987; Graves and Duvall 1993), females with their developing eggs (Gillingham 1987), neonates (Burghardt 1983), feeding individuals (Gillingham 1987; Gregory et al. 1987), female rattlesnakes with their recently born young (Butler et al. 1995; Duvall et al. 1985; Graves 1988; Greene 1997; Price 1988; Reinert and Zappalorti 1988), and denning aggregations (reviewed by Gregory 1982, 1984) suggest that snakes are more gregarious than previously thought. Gregory et al. (1987) report shedding aggregations in *Crotalus viridis*, but no details of these aggregations are provided. In this paper I describe aggregations associated with shedding by *Crotalus viridis concolor*, the midget faded rattlesnake.

These observations were made in June and July of 1997 and 1998 as part of a larger study on the population biology of *C. v. concolor* that took place from May–October 1997 and May–early July 1998. The study population was located near the east side of Flaming Gorge National Recreation Area, Sweetwater County, Wyoming (USA) at an elevation ca. 2000 m. During 1997 and 1998 each snake was captured at or near the den site and was measured to obtain SVL and mass, sexed via probing and everting the hemipenes (Gregory 1983), and given a unique identification via scale clipping (Brown and Parker 1976). In addition, radiotransmitters were implanted in some snakes. Reproductive status (pregnant vs. non-pregnant) of adult females was ascertained by palpation. Age status (i.e., adult vs. juvenile) was determined based on body size (adult females are at least 44.5 cm SVL, adult males are at least 39.5 cm SVL; unpubl. data from examination of museum specimens). During June to July of 1997 and 1998 I relocated snakes with transmitters daily. In addition, recaptured snakes without transmitters were recorded as they were encountered. At each recapture I noted whether the snake was pre-shed (signified by cloudy, bluish eyes and/or loose skin and a faded pattern), and if it was located within five meters of any other snakes. I also plotted the snake's location on a map of the study site. Distances between snakes were measured with a Roadrunner measuring wheel (accurate to 0.01 m; Keson). Any snake found to be within a five meter radius of any other was considered to be aggregated. If a snake was located with any other, I noted how many comprised the group, as well as the sex and age class (juvenile or adult) of each individual.

The following is an example of an aggregation of pre-shed individuals of *C. v. concolor*. On 13 June 1997 I found five adult *C. v. concolor* coiled within 2 m of each other. All five snakes had loose skin (i.e., the outer layer was loose and soon to be shed) and cloudy eyes, to varying degrees. Four of the five snakes (one adult male, one non-gravid female, and two gravid females) were coiled together in a large mass; the other snake, a gravid female, was 2 m away. These snakes remained together until 19 June 1997. Beginning on this date, individuals began leaving once they had completed shedding. By 8 July 1997 all individuals had completed shedding. Within a day of shedding the non-gravid female and the adult male moved more than 10 m away, whereas the gravid females remained at the same site.

Thirty-five *C. v. concolor* were captured between the beginning of June and the beginning of July in 1997 and 1998. Seventeen of these were found within five meters of other *C. v. concolor* (49%), and of these, 15 were pre-shed (88%). In contrast, 18 *C. v. concolor* were initially located more than five meters away from any other *C. v. concolor*, and of these, only three were pre-shed (17%). There was a significant association between shedding and being found in an aggregation ($\chi^2 = 17.93$, df = 1, $P < 0.001$).

Throughout 1997 and 1998 twenty snakes were captured prior to shedding. Of these snakes, 80% (16/20) were found in aggregations while they shed. Of the 16 shedding snakes that were found in aggregations, 14 were adults. Four individuals that were captured in the process of shedding did not aggregate to shed (i.e., were not found within 5 m of another snake). Of these, two were juveniles, one was a gravid female and one an adult male. It appears that most adults aggregate to shed, whereas juveniles may not (although the sample size of juvenile snakes is low).

Crotalus v. concolor at this site do not appear to hibernate in aggregations. Emergence at this site (Den 1), as well as another site ca. 15 km away (Den 2), took place at roughly the same time each year (mid–late May); however, the spatial distribution of snakes at each site differed. At Den 2 all snakes were found near a communal hibernaculum for 2–3 weeks after emergence. In contrast, snakes at Den 1 were not found together during this same time period. Thus, it seems that *C. v. concolor* at this site hibernate individually or in small groups, then come together to shed during June and July.

Additional evidence suggesting that snakes are not aggregated as a result of their recent emergence is provided by examining the dates that aggregated and non-aggregated snakes were captured. Between June and July, there is no significant difference between the dates when aggregated individuals versus non-aggregated individuals were caught (Mann-Whitney $U = 43.0$; $P = 0.20$). In addition, each aggregated individual (with the exception of gravid females) left its shedding site within a day of ecdysis; this suggests that shedding condition was an important determination of the location of a snake.

Although several shedding aggregations were observed between June and July 1997, only one small aggregation of two shedding snakes was observed in 1998. This aggregation took place on 26 June and occurred at a rock that was used in 1997 as a shedding site by multiple snakes at the same time. The weather was much colder during May and June of 1998 than in 1997. This may have delayed most shedding aggregations for a couple of weeks in 1998; the 1998 field season was cut short in early July and I was unable to verify this possibility.

If these shedding aggregations took place near hibernacula, I would expect that individuals would be found near these shedding sites year after year in the spring because snakes tend to use the same hibernacula each year (Gibbons and Semlitsch 1987; pers. obs. for *C. v. concolor*). However, in 1998, only two snakes were found at one of the 1997 shedding sites and both of these snakes were in the process of shedding. No snakes were found at any other 1997 shedding site from May–July 1998. In addition, no shed skins were found at these sites in 1998. This provides additional evidence that the aggregations are not simply the result of recent emergence of groups of snakes near the hibernaculum.

The aggregations that I have described were not for mating. Mating in this population began the first week of July during 1997 (no observations of mating behavior were made during 1998), which is near the end of the period when snakes were shedding. An adult male *C. v. concolor* did shed after the mating season began, yet he was found at a site where gravid females were gathered, and gravid females in this population have not been observed mating. In addition, shedding aggregations often consisted of multiple males with no females present. Groups with multiple males, non-gravid females,

and gravid females did occur. However, no mating behavior or male-male aggression was observed.

Adult *C. viridis* typically shed once per year, whereas juveniles shed more frequently and possibly less synchronously (e.g., Heyrand and Call 1951; King and Duvall 1990; Klauber 1972; Macartney et al. 1990; Ashton, unpubl. data). In addition, shedding of adult snakes occurs simultaneously during a period of two–four weeks (King and Duvall 1990; this study). However, shedding aggregations have not been previously described for this species (but see Gregory et al. 1987). One possible difference between *C. v. concolor* and other populations of *C. viridis* may be the availability of suitable sites for shedding. Thermal and hydric conditions seem to be very important to shedding snakes (Klauber 1972; Peterson et al. 1993). It is possible that there are fewer sites with adequate environmental conditions for shedding at the Wyoming study site than in other areas that *C. viridis* occupies. Another potential explanation is the decreased movements of *C. v. concolor* relative to other populations of *C. viridis*. While many populations of *C. viridis* migrate long distances each year, (Cobb 1994; Duvall et al. 1985; King and Duvall 1990; Macartney et al. 1988), *C. v. concolor* moves significantly less and does not migrate seasonally (Ashton, unpubl. data). In short, the decreased movements of adult *C. v. concolor*, coupled with a limited availability of sites with appropriate hydric and/or thermal conditions for shedding, may explain why shedding aggregations are observed in this population but not other populations of *C. viridis*.

Pre-shed *C. v. concolor* also may be actively choosing to aggregate with other individuals, possibly by following chemical trails of other pre-shed snakes (Gregory et al. 1987). It has been shown that aggregation reduces heat loss (Aleksiuk 1977; Graves and Duvall 1987; Myres and Eells 1968), and may decrease water loss (Duvall et al. 1985; Thomas 1965). Aggregating to decrease water loss may be especially important for snakes that are shedding because of the increased water loss associated with this process (Klauber 1972). Snakes also may be vulnerable to potential predators during shedding because of impaired function of the sensory system; they therefore may aggregate for increased protection from predators (Alcock 1993; Gregory et al. 1987). Thus, aggregations of shedding snakes may be actively sought out for the benefits of decreased water loss, heat loss, or increased protection from predators.

In conclusion, *C. v. concolor* formed shedding aggregations in June and July of 1997 and 1998. Shedding aggregations did not occur at communal hibernacula and mating behavior was not observed in these aggregations. These aggregations consisted mainly of adult snakes, which may be because of synchronous shedding of adults in this population. Other factors that may be important to the formation of shedding aggregations are decreased seasonal movements of *C. v. concolor* and the availability of sites with suitable environmental conditions for shedding. In addition, pre-shed snakes may be actively choosing to aggregate to decrease heat loss, water loss or predation while they shed.

The Visibility Hypothesis: An Explanation for the Correlation Between Habitat and Defensive Display in Snakes

PHIL SENTER
Department of Biological Sciences, Northern Illinois University
DeKalb, Illinois 60115, USA
e-mail: beccafaye@worldnet.att.net

Greene (1979) classified the defensive displays of snakes into three major categories—tail displays, horizontal head displays, and vertical head displays—and found that defensive displays in snakes are correlated with habitat. Tail displays, in which the tail's posture shifts such that the tail becomes more prominent, are typical of fossorial or terrestrial species. Horizontal head displays, in which the anterior part of the snake's body is flattened dorsoventrally, are typical of terrestrial species. Vertical head displays, in which the anterior part of the snake's body is dorsoventrally expanded, are typical of arboreal species (Greene 1979).

Within major snake taxa, defensive display appears to correlate better with habitat than with phylogeny (Greene 1979). The case of *Telescopus* illustrates this well. *Telescopus* spp. are terrestrial, employ horizontal head displays, and do not employ vertical head displays (Werner 1983). However, Cadle (1994) found that the successive outgroups to *Telescopus* among African colubrines are *Dasypeltis*, *Thrasops-Thelotornis-Dispholidus*, and *Philothamnus* (Fig. 1). These outgroups are composed of arboreal species which employ vertical head displays (Gans and Richmond 1957; Pitman 1974; Marais 1992). Apparently, both arboreality and employment of vertical head displays are primitive to the clade, and *Telescopus* has changed its defense display to match its change in habitat.

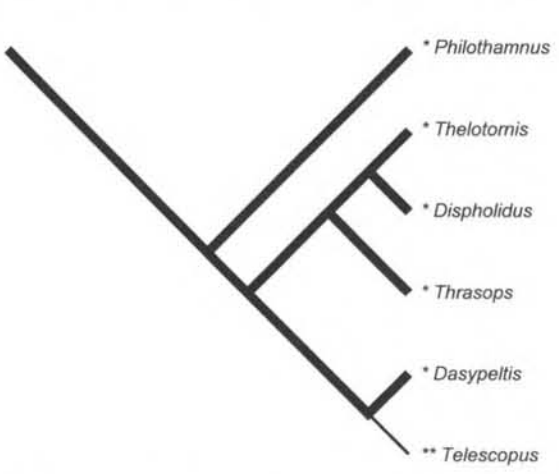

FIG. 1. Cladogram of African colubrines, modified from Cadle (1994). Bold line indicates arboreality, and thin line indicates terrestriality. Asterisk indicates vertical head display, and double asterisk indicates horizontal head display.

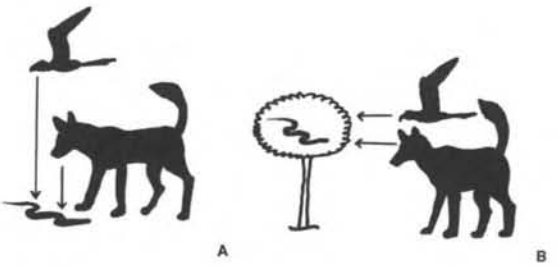

FIG. 2. The position of a snake influences the view obtained by an approaching predator. (a) A predator approaching a snake on the ground is more likely to obtain a dorsal view than a lateral view of the snake. (b) A predator approaching a snake on a branch is more likely to obtain a lateral view than a dorsal view.

As such, there is probably a selective advantage in employing a given defensive display only in the corresponding habitat. Greene (1979) did not hypothesize a specific advantage. I suggest that the advantage is related to the line of vision of approaching predators. Horizontal expansion maximizes the area of the snake in dorsal view, and is therefore most visible to a predator approaching from above. This is more likely to occur if a snake is on the ground than if the snake is above the ground, and is therefore more advantageous for a terrestrial snake than for an arboreal snake (Fig. 2a). Vertical expansion maximizes the area of the snake in lateral view, and is therefore most visible to a predator approaching from the side. This is more likely to occur if the snake is above the ground than if the snake is on the ground, and is therefore more advantageous for an arboreal snake than for a terrestrial snake (Fig. 2b). A tail raised by a snake in a tree may be hidden by leaves, whereas a tail raised by a snake on the ground will likely rise above ground litter. A tail display, then, will be more effective for a ground-based snake than for an arboreal snake.

The partitioning of defensive displays according to habitat among snakes is therefore probably not accidental. The partitioning appears to be related to the visibility of each display in each habitat. Unless future experiments refute this idea, the visibility hypothesis is a reasonable explanation for the correlation between habitat and defensive display in snakes.

Acknowledgments.—I thank Harry Greene, Laurie Vitt, and anonymous reviewers for improving the manuscript, and I thank Mata S. for her patronage.

Shell Disease in Turtles in the Rappahannock River, Virginia

There is rising concern about increased incidences of environmentally induced abnormal conditions and disease among turtle populations in the United States and Canada (Ernst 1995, 1997; Murphy and Collins 1983). Some problems may be related to an increase in environmental pollutants, which have been discovered in various populations of snapping turtles (*Chelydra serpentina*). These are the presence of chemical toxicants (PCBs, dioxins, furans, heavy metals, and pesticides) in turtle eggs, fat, liver, and other tissues (see discussion and lists of literature in Ernst 1995, 1997).

These pollutants were found through chemical testing, but other abnormal conditions in turtles have become visibly apparent. Fibropapilloma disease of marine turtles is occurring in alarming frequency in the form of unsightly tumors caused by a herpes-like virus that eventually leads to death of the turtle (Herbst 1994). Necrotic, spreading, bacteria-caused skin lesions have attacked pen-reared hatchling sea turtles (Wiles and Rand 1987; Witham 1973), and other captive turtles (Elkan and Reichenbach-Klinke 1974; Frye 1981; Kaplan 1957). A disease that results in emaciation and lesions on the plastron is suspected to be a cause of major population declines of the flattened musk turtle (*Sternotherus depressus*) in Alabama (Dodd 1988). Diseased shells have also been observed in wild desert tortoises (*Gopherus agassizii*) in southern California (Jacobson et al. 1994), and upper respiratory disease is a problem in some desert tortoise populations (Jacobson et al. 1991, 1995). More recently an apparent bacteria-caused shellrot disease was discovered in river cooters (*Pseudemys concinna*) and sliders (*Trachemys scripta*) from Georgia (Garner et al. 1997; Herrington and Herrington 1994; Lovich et al. 1996).

During the late winter and spring of 1993, several damaged turtles were collected from the Rappahannock River by Mills near his property at Falmouth, Stafford County, Virginia, USA. These turtles exhibited various stages of unnatural shell erosion. Mills continued to collect diseased turtles in the Rappahannock River until 1995. From 1993 to 1995 he recorded abnormal conditions in 14 turtles of six species: five painted turtles (*Chrysemys picta*), four redbellied turtles (*Pseudemys rubriventris*), three snapping turtles (*Chelydra serpentina*), one river cooter (*Pseudemys concinna*), and one stinkpot (*Sternotherus odoratus*).

In 1995 Mills brought diseased *C. picta* to Ernst for evaluation. Damage to the turtles seemed severe enough to warrant an attempt to determine the prevalence of the infection. This paper presents a preliminary study to determine the geographical area affected, the turtle species involved, and the extent of damage to the turtle population. The study area is the Rappahannock River from the I-95 Bridge Crossing at Fredricksburg, Virginia upstream to Raccoon Ford on Rt. 611 on the tributary Rapidan River.

Four sites along the Rappahannock River in Stafford County, Virginia, were sampled from July through early October, 1996. Site 1 was on the Woodland property, which lies on the north bank approximately 6 mi upstream from Fredericksburg and less than 0. 5 mi west of the Mills property (USGS Salem Quad.). Site 2 was upstream of Fredericksburg, near the I-95 bridge on the north bank. Site 3 was at England Run, approximately 1 mi west of Site 1. Site 4 was at the confluence of the Rappahannock River with its tributary, the Rapidan.

Most turtles were caught in hoop-net traps baited with fresh fish or canned sardines. *Pseudemys rubriventris* and *P. concinna* were captured by hand or with a dip net. Unfortunately, the summer of 1996 was one of wettest in the history of the Commonwealth of Virginia making field collection difficult at best. Several periods of heavy rain in July and August raised the river level to a depth in which trapping or other methods of collecting could not be conducted. Additionally, two hurricanes caused extensive long-term flooding on the river. Associated turbidity also prohibited hand capture. These setbacks resulted in a low number of captured turtles.

All captured turtles were identified to species, sexed, aged (when possible), weighed, and measured (carapace length, plastron length, abdominal scute length, second pleural scute length). Presence or absence of shell or skin damage was noted, and, if damage was present the turtle and its injury were photographed, and the extent of damage was quantified. Position of ectoparasites or algal colonies on the shell were also noted, because these may be contributing factors to shell damage. Undamaged turtles were marked for future identification using a series of code notches filed in the marginal scutes (Ernst et al. 1974) and released at the capture site.

Damaged turtles were brought to George Mason University (GMU) for further examination, and two severely diseased *Chelydra serpentina* and a *Pseudemys rubriventris* were dissected. Organ and tissue samples from the *P. rubriventris* were taken to Dr. John C. Harshbarger, at the Registry of Tumors in Lower Animals, George Washington University Medical Center, Washington, D.C., for tumor studies (see Lovich et al. 1996). The spleen had minute lesions scattered over its surface; the lung showed signs of pneumonia; septicemia and chronic inflammation were present within the spleen, liver, and digestive tract; and bacteria were found in blood within the heart. Harshbarger attributed some of the damage to vascular or intestinal helminths, but thought it strongly possible that microbes were involved (unfortunately, his laboratory does not identify microbes, and further identification of microbes will need to be conducted elsewhere).

Because of low sample size, data were tested only with a univariate probability test of binomial distribution (Conover 1980) with alpha set at 0.05. Data were tested against an expected 2% disease rate (Ernst, pers. obs., Pennsylvania; see below).

Twenty-eight individuals of five turtle species were collected in 1996. Of these, 14 (binomial test, $p < 0.005$) exhibited some form of damage: 10 *Chrysemys picta*, 4 damaged (40%); 8 *Chelydra serpentina*, 3 damaged (37.5%); 5 *Pseudemys rubriventris*, 100% damaged; 2 *Sternotherus odoratus*, 1 damaged (50%); 2 *Trachemys scripta*, 1 damaged (50%); and 1 undamaged *Pseudemys concinna*. Mills had previously found 14 damaged turtles from 1993 to 1996 (5 *C. picta*, 3 *C. serpentina*, 4 *P. rubriventris*, 1 *S. odoratus*, and 1 *P. concinna*). Between the two collections, 28 turtles had either visible shell or skin damage: 9 *P. rubriventris*, 9 *C. picta*, 6 *C. serpentina*, 2 *S. odoratus*, 1 *T. scripta,* and 1 *P. concinna.* Damage consisted of lesions on the skin of the head or limb sockets and lesions and eroded patches on the carapace or plastron. Grayish-white and pinkish skin sores resembled leprosy-like lesions described in Frye (1981), but some of the more reddish eroded patches on the shell more closely resembled multifocal petechial hemmorrahages (often caused by protozoans), also described by

Frye (1981). The skin lesions resembled those described from desert tortoises (*Gopherus agassizii*) by Jacobson et al. (1994). Kaplan (1957) reported the bacterial condition septicemic cutaneous ulcerative disease in turtles, which caused skin ulceration, lethargy, anorexia, filmed eyes, and general paralysis, and was extremely contagious and fatal in a captive colony. Description of the skin ulcers matched the ulcers found in Rappahannock turtles.

Based on combined data for all species captured, 20 of 31 adult turtles (64.5%) and 2 of 9 juveniles (22.2%) were damaged (the low incidence in juveniles may be misleading as some may have been too small to be captured in the nets used). Among sexed adults, 13 of 16 females (81.3%) were damaged, while 3 of 6 males (50%) showed abnormalities.

Of the four sites sampled (Table 1), damage was found in 55.5% (10 of 18) of the turtles at Site 2 (I-95), 50.0% (10 of 20) of those at Site 1 (Mills property, Falmouth), and in 100% (2 of 2) of the individuals caught at Site 4 (confluence of Rappahannock and Rapidan Rivers). Neither of the two turtles captured at Site 3 (England Run) showed damage. Although most damage seems to be in turtles at the two downstream collecting sites, this may be misleading since more effort to collect turtles occurred there than at the two upstream sites, preventing a statistical comparison of sites.

A total of 29 trap-days x 24 hours x 6 traps, or 2448 total trap hours were spent attempting to collect turtles during the study. An additional eight days were spent by GMU personnel and four more days by Mills attempting other means of turtle capture, for a total of 46 days in the field. The rate of turtle capture was exceedingly low, only 0.61 turtles per field day (0.96 per trap day), and only 0.6 turtles were observed basking per field day. During the course of the study GMU students saw only 12 turtles basking, and Mills another 20 in four days.

Both data sets indicate that a serious problem exists in the Rappahannock River. Usually, diseased individuals, or individuals showing the types of damage seen in this study, are rare in turtle populations (less than 2% of about 7000 individuals of six turtle species studied in Lancaster County, Pennsylvania, by Ernst from 1965 to 1988).

Also the diversity of species involved is high; six of six species in three families. Included are not only basking turtles (*Chrysemys*, *Pseudemys*, *Trachemys*), but also bottom dwellers that infrequently bask (*Chelydra*, *Sternotherus*). During a similar study on the Flint River, Georgia, only basking turtles were found with shell erosion (Lovich et al. 1996). The damage to Rappahannock River turtles does not resemble that of the Georgia turtles and is not as severe. That *Pseudemys rubriventris*, a strict herbivore as an adult (Ernst et al. 1994), showed a 100% incidence of damage during this study may indicate an ecological correlation. It is possible that damaged tissues on the turtles are the result of secondary bacterial or protozoan infection(s) after initial chemical pollutant damage to skin and shell scutes. From studies elsewhere, it seems that increases in some pollutants (or introduction of a new pollutant) initiates damage to turtles, which then allows viruses, bacteria, protozoa, or fungi to invade, causing greater damage and even death of the individual. Environmental factors, such as increases in ultraviolet radiation, may cause damage, especially in basking species, as found in recent studies on declining amphibian species.

As the data stand after the 1996 study, due to small sample size, all that can be accurately inferred is that the damage is widespread among turtles in the Rappahannock River (6 of 6 species collected), it is of high incidence (about 50% of individuals), and it extends along the river from Falmouth/Fredericksburg upstream to the confluence of the Rappahannock and Rapidan Rivers.

A serious health problem exists among the turtle species in the Rappahannock River. If a higher than normal incidence of disease exists in the turtles in the Rappahannock River, it may be an indication of a much more widespread problem that probably is affecting other species as well.

Acknowledgments.—We thank John C. Harshbarger for his help with examination of diseased turtles, and George R. Zug of the Smithsonian Institution for advice given during the study. Turtle surveys were funded through a contract with the Virginia Department of Game and Inland Fisheries.

Aerial surveys often are used to find and enumerate wildlife, particularly large or conspicuous species such as waterfowl, marine mammals, and terrestrial megavertebrates (Caughley 1977; Eggeman et al. 1997; Mattson 1997; Pojar et al. 1995; Yoshida et al. 1998). Few studies of amphibians and reptiles have employed aerial surveys (e.g., Rhodes and Wilkinson 1994; Shoop et al. 1982) because most species are small, secretive, and difficult to spot from aircraft. In addition, studies of amphibians and reptiles historically have received limited funding (Gibbons 1988), making aerial surveys too expensive for most researchers. However, concern about a potential global decline in amphibian populations (Blaustein and Wake 1990) and increasing use of herpetofauna in environmental assessment (e.g., Beiswenger 1988; Bonin et al. 1997) has heightened interest in these taxa. Many large-scale surveys of amphibians and reptiles have been published (e.g., Bradford 1989; Drost and Fellers 1996; Hecnar and M'Closkey 1996; Spillers and Speake 1988) or are underway. Aerial surveys can be useful for biologists searching for amphibian and reptile habitat. Here we describe an economical method to locate amphibian breeding ponds from a helicopter. Our technique could be used for other small-scale amphibian and reptile habitat, such as alligator nests, rattlesnake dens, gopher tortoise borrows, and talus slopes harboring salamanders.

As part of an ongoing wetland research project, we had to locate 31 wildlife ponds (approx. 19 x 4 x 1.25 m deep) scattered in nine groups within the 100,000 ha (250,000 acre) Francis Marion National Forest (FMNF), Charleston and Berkeley Counties, South Carolina, USA. The wildlife ponds were excavated with a bulldozer in June 1982 and June 1983, but had not been studied since their creation. We were given approximate pond locations on FMNF compartment maps, standard U.S. Geological Survey (USGS) topographic maps revised to show tree stands. Pond locations were not marked on the ground by paint blazes on trees or permanent markers, and the ponds were too small to appear on National Aerial Photography Program (NAPP, USGS) color infrared photographs taken from aircraft flying at 6100 m.

Standard methods for locating the ponds were inefficient. Ground searches conducted December–January were hampered by dense pocosins (shrub bogs), which an early settler accurately described as "being very wet and low lands and so full of Cane and Underwood, that there is no passing through them, many of which are several miles in length" (Wells 1932). Undergrowth regenerating after Hurricane Hugo in 1989 and a subsequent moratorium on prescribed burning made ground searches very difficult. The heavy vegetation concealed most ponds until we came within a few meters of them; we almost fell into several before realizing they were underfoot. After a month of ground searches, including one that deployed 22 students in an intense but unsuccessful search for a pond just 245 m from a major road, we had located just thirteen ponds (42%).

We explored the use of alternative aerial techniques to locate the ponds. We contracted a local helicopter service with experience operating over the FMNF to do low-level reconnaissance. Usually, they use a very labor and time-intensive method: after spotting the desired location from the air, the helicopter hovers and directs a ground crew to the site using two-way radios. In more open terrain, Cyalume Lightsticks™ (Omniglow Corporation, Novato, California, USA) are dropped in a line between the ground crew and their target. Both methods require coordinating ground crews with the helicopter pilot and spotters, and use considerable helicopter time, which costs US $600/h in our area. We knew from prior experience that it could take ground personnel over an hour to traverse 300 m through the dense vegetation, making this method far too helicopter-intensive. We needed a more cost-effective technique.

As a solution to these problems, we chose a dual strategy of using the helicopter's global positioning system (GPS) to record each pond's position, and then dropping an emergency strobe nearby to broadcast its exact location. The strobe manufacturer (Nordic Technologies, Salt Lake City, Utah, USA) stated that the light could be seen for 5 km under unobstructed viewing conditions and would initially flash 50–70 times/min, with the rate steadily declining until the "D" cell expired after 72 h. We attached the emergency strobes to homemade, 56 cm (22") square parachutes made of bright red nylon fabric. We tied bright pink nylon cords (56 cm long) to the fabric with overhand knots, and to the strobe attachment pin with two half hitches. This knot was further secured with red duct tape. The result was an inexpensive (total cost approx. US $20), highly visible unit that survived a 13 m test drop and was neutrally buoyant with the battery installed. We expected that the weak overhand knots securing the cords eventually would come loose from the parachute material, allowing us to retrieve strobes caught in trees. We planned to find the ponds at night using headlamps, a compass and hand-held GPS (GARMIN GPS 45XL Personal Navigator™, GARMIN Corporation, Olathe, Kansas, USA), homing in whenever possible on the flashing strobe. We then would mark a trail with vinyl flagging to allow easy return. We notified the local sheriff and air traffic controllers of our plans, so they would not waste time responding to reports of rescue beacons flashing in the FMNF.

We used our method on two occasions. Each time, we flew parallel search lines 5–60 m above the trees in a Bell Jetranger BIII helicopter with its doors removed. We used laminated aerial photographs (NAPP 1991 or 1994) to navigate; aerial survey targets placed at known road junctions served as ground reference points. Aerial searches initially were centered on the ponds' mapped locations but we expanded the search radius when necessary. Both the pilot and two observers searched for ponds. Even with the entire region heavily flooded and pond margins supporting natural growth of pocosin shrubs, we recognized the distinctive rectangular shape of the manufactured ponds and the small dirt mounds pushed up by the bulldozer, which were now covered by dense young pine trees. When a pond was located, we hovered, recorded its coordinates from the helicopter's GPS (Apollo Model 360), and tossed out a strobe. We noted the strobe's landing position (in the water, on the ground, or in a shrub or tree) and recorded the compass bearing and approximate distance from the beacon to the pond. If we failed to find a pond after 2–3 overlapping searches, we quit and flew to the next site.

We returned to the FMNF at night, scanning each area for flashing strobes. We saw about one-half of the strobes from roads, and simply hiked to the beacon, using a compass to maintain a straight course when the flashing light was obscured by vegetation. We used our handheld GPS and the coordinates provided by the helicopter's unit to navigate to the remainder. We often lost the GPS signal when overhead satellite coverage was poor; at other times, dense thickets blocked satellites from view. We overcame these problems by using the initial GPS waypoint bearing (the compass direction from our access point to the pond, taken from the helicopter's GPS), and navigating with a compass. This proved highly accurate, usually bringing us within 50 m of the pond. By then we usually could see the strobe, even if it was on the ground or was emitting a weak light after several days of operation. From the strobe we followed the compass bearing (recorded while in the helicopter) to the pond. Without the strobe, we would have been forced to search > 31,416 m^2 of terrain, because the GPS signal became unreliable at distances below about 100 m. In more open forest compartments, daylight searches quickly found the bright red parachute.

We made only two adjustments to our technique between flights. The first was using a commercial aerial survey target (Forestry Suppliers, Inc., Jackson, Mississippi, USA; US $17) instead of yellow vinyl flagging to mark ground locations. The black and white commercial target proved much easier to spot while flying search lines. The second adjustment was pitching the parachute and strobe directly into the tallest nearby tree, instead of allowing it to freefall. This modification ensured the beacon was seen from afar, instead of sometimes landing in low-lying shrubs.

Our methods proved highly successful. We located 14 of the 18 missing ponds (78%) in two flights totaling 3.75 h. Several ponds located by aerial search were far from their mapped locations (> 340 m), as determined later using more sophisticated GPS units with submeter accuracy (Sokkia GIR1000, Sokkia Corporation, Overland Park, Kansas, USA). These ponds would have been virtually impossible to find with a ground search. In addition, the aerial survey indirectly helped locate three additional ponds. We discovered one while orienteering to a beacon, and two more using the USFS compartment maps with some ponds now precisely plotted using GPS coordinates. From the spatial pattern on the maps, we deduced that one pond was located beyond our aerial search radius, and another had been misplotted on the FMNF map (i.e., four ponds that formed a backwards "L" pattern actually had their long axis running east-west instead of north-south). Thus, in just six days we found 17 of the 18 (94%) missing ponds. To date, we also have recovered > 50% of our strobes.

Our aerial search technique proved successful under adverse spotting conditions, including a dense shrub layer in a forest regenerating from a major hurricane, severe local flooding, and dangerously gusting winds that forced one pilot to end a search. Despite these hindrances, the helicopter enabled us to find more ponds in a few hours than we located in a month of ground searches. The cost of finding a pond was about 25% lower using our aerial search technique than reconnoitering on foot (approx. US $220 versus $300/pond), and far less frustrating. Helicopter time is less expensive (US $100–200/h) in regions served by multiple companies, making aerial surveys elsewhere likely to be more economical than our study suggests. Using both GPS coordinates and the flashing strobes ensures the method will work, even in dense forest or mountains. In hospitable terrain, it will be easy to locate, mark, and access amphibian and reptile habitat, making helicopter surveys a rapid and cost-effective method for many herpetological studies.

Acknowledgments.—We thank HeliEast Inc. Charter & Aerial Productions, and especially pilots Scott Newsome and Scott Yackel, for their assistance conducting this survey and returning three herpetologists safely back to *terra firma*. We also thank the staff of the Francis Marion National Forest, particularly District Ranger Glen Stapleton and Wildlife Biologists Danny Carlson and Craig Watson, for aiding our studies. The alligator snapping turtle (*Macroclemys temminckii*) is found along Gulf of Mexico drainages of the southeastern United States from Texas through Florida. In recent decades, population numbers have declined throughout the turtle's range as a result of habitat alteration and unregulated harvesting for meat and related products (Pritchard 1979, 1989). In response to this decline, commercial harvest is prohibited in every state where *M. temminckii* occurs, except Louisiana.

Because the common snapping turtle (*Chelydra serpentina*) is still relatively abundant and not subject to strong harvest regulations, meat from illegally harvested alligator snapping turtles may be sold as common snapper. In order to enforce restrictions on the harvest and sale of alligator snapping turtle meat, wildlife managers must be able to identify *M. temminckii* products quickly and with a high degree of confidence. One traditional way to identify meat products is through monoclonal antibodies designed for each candidate species. However, these antibodies are expensive to develop and maintain, and have limited utility with cooked or prepared meat products. An emerging alternative is to use genetic markers identified with polymerase chain reaction (PCR) methodology (Baker et al. 1996; Encalada et al. 1994; Guglich et al. 1994). These markers can be applied to very small tissue samples, dried skin, partially degraded meat, and some cooked products.

At the request of the Florida Game and Fresh Water Fish Commission, we developed a simple genetic test to differentiate meat and by-products of *M. temminckii* from those of *C. serpentina*. This assay is quick, relatively inexpensive, and may provide results of sufficient quality to be considered evidence in a court of law.

We extracted DNA with standard phenol-chloroform procedures and resuspended the isolations in 0.5 ml TE buffer (Hillis et al. 1996). Primers employed by Lamb et al. (1994) were modified to amplify products from a portion of the $tRNA^{PRO}$ gene and adjoining 5' end of the mtDNA control region in chelydrids (5' TCT TCC TAG AAT AAT CAA AAG 3' in the $tRNA^{PRO}$ gene; 5' ATG ACC CTG AAG AAA GAA CCA 3' in the central control region). We performed PCR reactions (50 µL) with a Biometra Personal Cycler under the following conditions: 5 µL 10x buffer, 3 mM $MgCl_2$, 0.5 mM dNTPs, 1 µM each primer, 0.5–1 unit *Taq* DNA polymerase, and 2 µL of the DNA extractions. Amplifications (35 cycles: 1 min 94°C, 1 min 50°C, 2 min 72°C) were purified with Ultrafree-MC 30,000 filters (Millipore).

The search for an appropriate restriction-site marker was based on published mtDNA control-region sequences of the two turtle species (N = 158 for *M. temminckii*, Roman et al. 1999; N = 66 for *C. serpentina*, Walker et al. 1998). The common snapping turtle had very low mtDNA diversity, whereas *M. temminckii* had considerable interdrainage variation. Nonetheless, the high divergence between the two species (d = 0.1027–0.1253) allowed for ready identification of diagnostic restriction sites using Sequencher 3.0 software (Gene Codes Corporation). We employed three enzymes for the restriction endonuclease assays: *Mbo*I, *Bsp 1286* I, and *Hpa*II (New England BioLabs). Five µL of PCR product was digested for 90 min at 37°C, with 7.5 units of enzyme in 1.0 µL of 10x buffer and 3.25 µL H_2O. Digestion products were separated and visualized on 2% agarose gels, using ethidium bromide staining and UV illumination.

Each of the three enzymes proved diagnostic in distinguishing the two chelydrid species (Fig. 1). An unanticipated benefit was that one of the three enzymes, *Hpa*II, differentiated *M. temminckii* samples in western drainages from those of eastern drainages (Fig. 1; see also Roman et al. 1999). The 220 bp and 190 bp fragments observed in western samples (Louisiana, Alabama, and Pensacola Bay drainages, N = 25) contrasted with a 410 bp fragment found in samples from the Choctawhatchee, Econfina, Apalachicola, and other eastern drainages (N = 16).

Independent analyses confirmed that the genetic assay is easy to use, reliable, and robust. A survey of 30 *C. serpentina* was conducted at the University of Georgia by DW to confirm restriction-site patterns for enzyme *Hpa*II. The restriction profiles for enzymes *Mbo*I and *Bsp 1286* I were confirmed at the University of Florida with *C. serpentina* (N = 8) and *M. temminckii* (N = 10) from throughout its range. In each instance, the enzymes produced the predicted fragment pattern.

In cases where suspected illicit products are found (such as the *M. temminckii* profiles in Fig. 2), it may be desirable to corroborate these results through direct sequencing (Roman and Bowen 1999). These sequences can be compared to control-region haplotypes of *C. serpentina* and the western, central, and eastern lineages of *M. temminckii* posted on GenBank (accession numbers AF029986 and AF056522-AF056524). The drainage-specific haplotypes of the

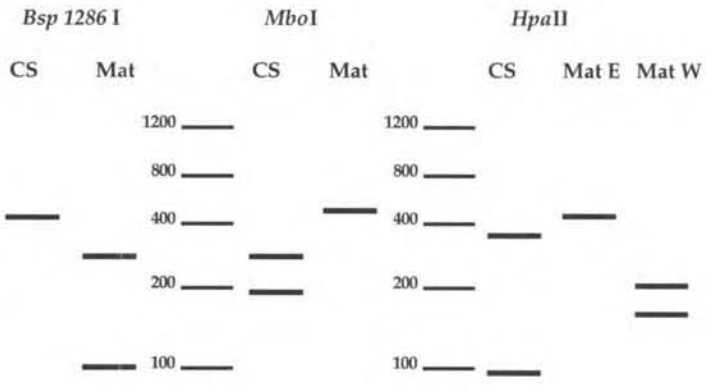

FIG. 1. Schematic representation of *Bsp 1286* I, *Mbo*I, and *Hpa*II digests of the 424 bp control-region fragment in *C. serpentina* (CS) and *M. temminckii* (Mat). *Bsp 1286* I cuts *M. temminckii* but not *C. serpentina*; *Mbo*I cuts *C. serpentina* but not *M. temminckii*. Note the 220 bp and 190 bp fragments on the extreme right lane of *Hpa*II. These fragments distinguish western *M. temminckii* samples (of the Pensacola Bay drainage westward) from eastern and *C. serpentina* samples. The third and sixth lanes represent molecular weight standards.

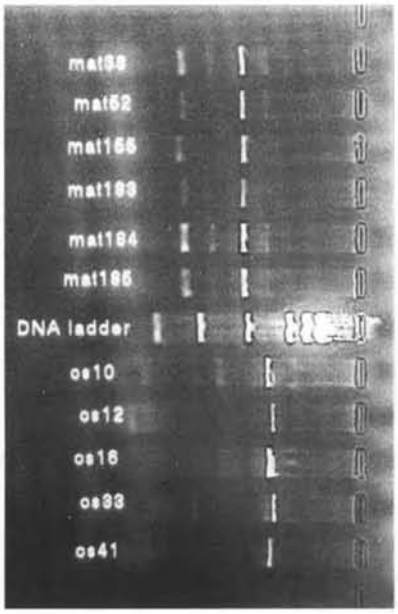

FIG. 2. mtDNA digestion profile of *Mbo*I. Restriction fragments were separated on 2% agarose gels and visualized by ethidium bromide staining and UV illumination. In states where commercial trade in alligator snapping turtle products is prohibited, profiles matching the first six lanes would indicate an illegally harvested turtle. Lane 7 is a molecular weight standard (Low DNA Mass Ladder, Gibco BRL) with fragment sizes as indicated in Fig. 1.

alligator snapping turtle may assist wildlife managers and enforcement agencies in identifying region of origin of confiscated material (Roman et al. 1999).

With the growing genetic database available on the Internet, additional turtle species can be readily distinguished using sequencing data. Samples that do not amplify with our control-region primers can be sequenced with cytochrome *b* primers and compared to more than 30 species of turtle currently posted on GenBank. The broad range of taxa available to wildlife forensic scientists will be useful for litigation and surveying the marketplace, even in the absence of suspicious circumstances. The susceptibility of many turtle species to unsustainable commercial harvests makes such surveys of eminent concern.

Acknowledgments.—We thank Paul Moler for motivating this study. Steve Santhuff and Paul Moler provided snapping turtle samples. Ginger Clark and Anna Bass assisted in the lab. This work was supported by funds from the Florida Game and Fresh Water Fish Commission, the U.S. Fish and Wildlife Service, and grants to J.R. and B.W.B. from the National Science Foundation.

HERPETOLOGICAL HUSBANDRY

An Investigation of Obligate Oophagy of *Dendrobates pumilio* Tadpoles

#1 Canal Street, New Orleans, Louisiana 70130, USA

Weygoldt (1980) first described the extensive parental care of *Dendrobates pumilio* in a study of captive frogs. Since then, *D. pumilio* tadpoles have been described as obligate egg-eaters because of their reduced mouthparts and behavioral observations made in the laboratory and the field (Brust 1993; Myers and Daly 1983; Weygoldt 1984). The obligatory oophagy of these tadpoles is shared by several unrelated lineages of anurans (e.g., the hylids *Anotheca spinosa*, *Osteocephalus oophagus*, and *Osteopilus brunneus*, and the microhylid *Hoplophryne rogersi*) (Jungfer 1996; Jungfer and Schiesari 1995; Lannoo et al. 1987; Noble 1929, respectively).

Dendrobates pumilio, a small, diurnal dendrobatid, ranges from northern Nicaragua through Costa Rica to western Panama. Many aspects of the reproduction and parental care of this species have been studied extensively (Brust 1993; Donnelly 1989a,b; Limerick 1980; Myers and Daly 1983; Weygoldt 1984). Reproduction in *D. pumilio* involves deposition of eggs in leaf litter. Males guard the eggs for about seven days, after which females return to the oviposition site to carry the tadpoles to a phytotelm (water-filled leaf axil). At La Selva Biological Station, Costa Rica, the preferred plants for tadpole deposition are *Dieffenbachia* sp. (Araceae) and bromeliads (Bromeliaceae) (pers. obs.). Females deposit only one tadpole per leaf axil. The females visit each tadpole every 1.6–4.2 days to deposit from one to five unfertilized eggs for a period of six to eight weeks until metamorphosis is completed (Brust 1993).

Female *Dendrobates pumilio* rear tadpoles in leaf axils that are relatively small spaces. In this small area, shared by many organisms for rearing larvae (e.g., mosquitoes and chironomid flies), arboreal tadpoles potentially may benefit from eating young predaceous insect larvae, thereby preventing the development of future predators (Caldwell 1993).

This study addressed whether *Dendrobates pumilio* tadpoles consume items other than conspecific eggs. The first part of the study was performed in a field laboratory where we tested the ability of wild-caught tadpoles to eat insect larvae commonly found in their microhabitats. The second part involved F_1 generation captive offspring of *D. pumilio* and tested the ability of the tadpoles to consume alternate food items. Because herpetoculturists have had success raising *Dendrobates histrionicus* and *D. lehmanni* tadpoles on chicken egg yolk (Zimmermann and Zimmermann 1980), captive *D. pumilio* tadpoles were offered raw chicken egg yolk and the eggs of other species of frogs (including eggs of congeneric *Dendrobates auratus*).

Field studies.—On 26 July 1997, 14 tadpoles were collected from the forest at La Selva Biological Station, Heredia Province, Costa Rica. Seven were obtained from leaf axils of *Dieffenbachia*, and seven were collected from bromeliads. A disposable pipette was used to extract the tadpoles from their microhabitats, and the volume of each leaf axil was measured with a syringe. Leaf-axil height above the ground was recorded, and each axil was marked with flagging tape to facilitate the eventual return of each tadpole to its respective axil. The developmental stage of each tadpole was determined (Gosner 1960). Tadpoles were housed in a field laboratory at ambient temperature and under natural light. Each tadpole was kept in a glass test tube containing the water from the leaf axil in which it had been living. An electronic pH meter (Corning® pH Meter 245) was used to measure the pH of each water sample. Midge (Chironomidae) and mosquito (Culicidae) larvae used in the feeding trials were collected from the same plots where the tadpoles had been collected.

After a two-day starvation period in the laboratory, each tadpole randomly was offered either one chironomid (ca. 3–5 mm long) or one mosquito (ca. 4–5 mm long) larva. The test tubes were observed for two hours and the tadpole behaviors noted. The presence or absence of prey items was recorded 24 h later and uneaten larvae were removed from the test tubes. The condition (e.g., alive, dead, intact, or damaged) of the removed insect larvae was recorded. One hour later, each tadpole was offered a larva of the type that had not been offered previously, and the test tubes were again observed for two hours. The presence or absence of fly larvae was noted 24 h later. The tadpoles then were returned to their original capture sites. Wild-caught *D. pumilio* tadpoles consumed neither chironomid fly larvae nor mosquito larvae. During our two-day observations the tadpoles never struck at or attempted to capture the dipteran larvae. In addition, the insect larvae showed no signs of damage that may have resulted from feeding attempts by the tadpoles.

Laboratory studies.—The following assays were performed in order to improve the captive productivity of *D. pumilio* as part of the captive-breeding program at the Aquarium of the Americas in New Orleans, Louisiana. The adult frogs in the collection were wild-caught in April 1983 in a small stand of remnant primary forest, east of Guapiles, Limon Province, Costa Rica (ca. 40.3 km from the La Selva Biological Research Station). The tadpoles used in this study were the F_1 generation of these wild-caught individuals.

After hatching, *D. pumilio* tadpoles were housed separately in clear plastic 7.5 x 15.0 x 12.5 cm boxes filled with 2.5–5.0 cm of rainwater with a tannic solution additive. The tannic solution ("tadpole tea") is adapted from a protocol used by fish culturists to decrease bacterial and fungal growth in fish water (Scheel 1975). See the appendix for the recipe for this solution.

The laboratory was 23°C throughout the period of study. In the first trial, raw chicken egg yolk was fed to 28 tadpoles for a period of up to 10 months. Next, three sets of eight additional tadpoles each were offered eggs of one of the following local frog species: *Rana grylio* (Ranidae), *Bufo valliceps* (Bufonidae), and *Hyla cinerea* (Hylidae). The eggs of these frogs were collected in rearing ponds from a fish farm in Lacomb (St. Tammany Parish), Louisiana, USA. For the first trial, the eggs were collected and quick-frozen to reduce the time required for egg collection. After the tadpoles expressed no interest in thawed frog eggs, fresh eggs of the same taxa were offered. In the last trial, 41 tadpoles were offered fresh *D. auratus* eggs over a five-month period. These eggs were obtained from the second author's captive breeding production, which has an ongoing surplus of *D. auratus* eggs. The frog eggs were offered in one of two ways: whole or with the jelly coats removed prior to feeding. After several weeks, it was observed that tadpoles fed *D. auratus* eggs preferred them with the jelly coats removed; therefore, only eggs of this type were used for the remainder of the study.

Each of the tadpoles of *D. pumilio* was offered one frog egg (or an equivalent portion of raw chicken egg yolk) per day and was observed for 20 min after food introduction. Each food type (except the chicken egg yolk) was left in the water with the tadpoles for 24 h, after which time any remaining food was removed. The chicken egg yolk fouled the water and was removed after eight hours. Feeding responses were recorded, and times to metamorphosis were noted.

Tadpoles ate no local frog eggs, but consumed chicken egg yolk and congeneric eggs; this differential food consumption was significant ($P < .000001$; Fisher Exact Test). Normally, time to metamorphosis in captivity is approximately 10 weeks, but when fed chicken egg yolk, the tadpoles remained in Gosner stage 34–36 well into their tenth month. None of the tadpoles offered local frog eggs survived to metamorphosis. Of the 41 *D. pumilio* tadpoles fed eggs of *D. auratus*, 7.3% survived (N = 3). Survival is defined as the percent of tadpoles that reached metamorphosis. The average time to metamorphosis for these individuals was 154 days.

The lack of interest shown by tadpoles when offered local frog eggs contrasted markedly with the strong feeding response that was elicited by the presence of eggs of *D. auratus*. The tadpoles wriggled their tails and frantically darted about as soon as an egg was added to their container. This "dancing" behavior is identical to that displayed by wild tadpoles of *D. pumilio* when they solicit egg laying from their mother (Brust 1993). The tadpoles fed congeneric eggs were the only ones to metamorphose. Tadpoles fed eggs of *D. auratus* had development periods comparable to those of captive, parent-raised tadpoles. Although the percent survival of these individuals is low (7.3%), it is close to the percent survival of captive, parent-raised tadpoles (8%) (Hiler, unpubl. data).

Although it has been demonstrated by Brust (1993) that *D. pumilio* tadpoles rely solely on conspecific eggs provided by their mothers for development there have been no published data indicating rejection of fly larvae. The first part of this study supports literature that states that tadpoles of *D. pumilio* are obligate egg-eaters that do not consume fly larvae that coexist with them in phytotelmata. The second part of this study suggests that captive-raised *D. pumilio* tadpoles can distinguish between congeneric eggs and those of more distantly related species. Although captive *D. pumilio* tadpoles also will eat chicken egg yolk, this diet does not appear to offer the nutrition necessary for proper development.

Feeding congeneric eggs to tadpoles is a labor-intensive technique; however, in raising rare or endangered species of obligate egg-feeding dendrobatids, it may be the only available option.

Acknowledgments.—J. Pramuk thanks J. P. Caldwell for recommending the field component of this project; M. Maple for her assistance in the field; and the Organization for Tropical Studies and the Natural History Museum, The University of Kansas, for financial support. We thank J. P. Caldwell, A. Clarke, W. E. Duellman, J. Parmelee, H. da Silva, A. Sproston,

and L. Trueb who reviewed the manuscript and provided many helpful comments.

Appendix.—Recipe for making tannic solution additive for tadpole water: Combine 28 g of alder "cones" (*Alnus* sp.), 28 g German Peat Moss (Eheim Ltd.), and two liters rainwater in a medium saucepan and heat to a low boil. Simmer the mixture for 20 minutes and allow the extract to cool. Filter the extract through a strainer. Dilute 12 ml of the extract with 19 liters of rainwater (or with enough water to yield a light amber solution). This recipe will yield approximately 152 liters of tadpole water.

Preferential Coprophagy in Neonate Chuckwallas (*Sauromalus*, Lacertilia, Iguanidae)

RICHARD R. MONTANUCCI
Department of Biological Sciences, Clemson University
Clemson, South Carolina 29634-1903, USA
e-mail: rrmnt@Clemson.edu

The family Iguanidae (*sensu* Frost and Etheridge 1989), comprises an assemblage of predominantly herbivorous lizards, characterized by having an enlarged, septate colon where fermentative cellulose digestion occurs (Iverson 1982). The gut microbial symbionts (required for the breakdown of cellulose into simple compounds) are not passed directly from the parents to their offspring. Instead, as noted by Troyer (1982), hatchlings of *Iguana iguana* disperse into the forest to associate with adults, whereupon they encounter and eat the adults' feces, thus becoming inoculated with gut symbionts.

Coprophagy in neonate chuckwallas (*Sauromalus obesus*) was first reported by Montanucci (1997). Herein, I comment further on coprophagic behavior in chuckwallas, and show by means of a simple choice test, that it is not random behavior, but entails preferential feeding that occurs soon after hatching.

Observations are based on a total 54 captive-bred neonates between the ages of 4 and 7 days. The hatchlings were produced during the 1997 and 1998 breeding seasons by 8 breeding pairs from 7 localities. Captive management and propagation of the chuckwallas followed procedures described in Montanucci (1997). The hatchlings (which had not been previously fed) were simultaneously offered two identical food plates: one of finely chopped romaine lettuce, the other containing day-old, air-dried feces from adult chuckwallas. Each hatchling was tested individually for its food choice and any subsequent feeding behavior noted during a five minute observation period. The food plates were placed in front of, and equidistant from, the hatchling. The feeding trials were performed inside a "40 breeder" tank (ca. 91.5 x 45.8 x 43.3 cm), lined with white paper towels as flooring material. A 75-watt indoor flood lamp was mounted near one end of the cage as a heat and light source. The results of the feeding trials are summarized in Table 1.

The chuckwalla's approach to the food plates was apparently stimulated by visual cues. Subsequent feeding behavior involved chemosensory stimuli when the food was tongue-flicked. The majority (42 of 54; 77.7%; $\chi^2 = 16.666$; $P < 0.001$) of the hatchlings attempted to eat feces first over lettuce. Although the lettuce appeared to be more conspicuous visually than dried feces, only 6 of the 42 hatchlings were attracted to the lettuce, tongue-flicked it, but then selected the feces. Among the 12 hatchlings that ate lettuce first, all consumed only a small amount (1 to 3 small pieces), and then 8 lizards focused their attention on the dried feces, never returning to the plate of lettuce. Only 4 hatchlings failed to demonstrate any interest in the feces during the observation period. Several hatchlings, when returned to a holding box after the feeding trials, were observed biting the brown tail tips of their siblings; they may have mistaken the tail tips for fecal pellets.

After completion of the initial trials, two sets of siblings (7 from Agua Caliente, Arizona; 3 from Salt River Mts., Arizona) were observed as groups for a 20 minute period during which the plates of lettuce and feces remained in the cage. During this time, the hatchlings ran rapidly about the cage, periodically basked under the heat lamp, and scampered past, or over, the two food plates. They showed little interest in the plate of lettuce, but occasionally stopped to tongue-flick the feces (or tongue-flicked while running),

and often grasped fecal pellets in their jaws and repeatedly shook them. The hatchlings' interest in the fecal pellets gradually waned after 15 minutes, and by 20 minutes, the plate of dried feces was largely ignored. However, thirteen days later, a plate of dried feces was placed in the cage with the 7 Agua Caliente hatchlings. Two of the hatchlings again tried to eat the feces, but the others showed no interest.

TABLE 1. Food choice of hatchling chuckwallas.

Locality	(N)	Ate lettuce first	Ate feces first
Agua Caliente, AZ	(19)	4	15
Crater Range, AZ	(4)	0	4
Picacho Mts., AZ	(8)	1	7
Salt River Mts., AZ	(3)	2	1
Apple Valley, CA	(6)	4	2
Desert Center, CA	(9)	0	9
Palm Springs, CA	(5)	1	4
Totals		12	42

The feces of adult chuckwallas were generally too large for the hatchlings to ingest. However, the neonates seized the dried fecal droppings in their mouths, usually at the tapered ends of the pellets, attempted to bite them, and subsequently shook them violently. In some instances, this repeated shaking behavior (up to 8 bouts observed), successfully led to breaking off small bits of the fecal pellet which could be ingested. Whether ingestion of fecal material is necessary for inoculation of symbionts remains conjectural. Only a few hatchlings succeeded in actually eating bits of fecal material, but all lizards eventually demonstrated normal food digestion. Hence, the repeated "mouthing" of the fecal pellets was probably sufficient to inoculate the neonates with symbiotic microbes.

The gut symbionts of iguanas are obligate anaerobes and presumably do not survive long outside the intestinal environment. Thus, Troyer (1982) concluded that a brief association between juvenile and adult iguanas was necessary to effect microbial transfer. While the microbial symbionts in chuckwallas have not been studied, presumably they are also anaerobes. The strong social component to chuckwalla behavior (Berry 1974), would facilitate parent to offspring transfer (via coprophagy) of these colonic microbes.

Coprophagy was not observed during the subsequent months that the hatchlings were reared, except on two occasions. A juvenile was observed tongue-flicking and briefly "mouthing" a fecal pellet from a sibling that shared its cage, and another hatchling actually ate an entire fecal pellet. These instances occurred after a two-day period of food deprivation and may simply have been due to hunger.

Acknowledgments.—Chuckwallas were collected in California under scientific permit numbers 0301 and 9044, and in Arizona under several nonresident hunting licenses. I wish to thank Jay Chance, Jerrold J. and Martin J. Feldner, Tom Greb, Ellen M. Kiley (USFWS), Jim McGuire, Tony Mills, Lester Milroy III, Regis Opferman, and Jeff Wines for help in procuring adult chuckwallas. T. Greb assisted in recording observational data.

CAUDATA

PLETHODON IDAHOENSIS (Coeur d'Alene Salamander) **SKELETAL ABNORMALITY.** Natural occurrence of scoliosis has been reported in *Plethodon glutinosus* (Marvin 1995. Herpetol. Rev. 26:30). Herein we report a similar condition in an adult male (4.2 cm SVL) *Plethodon idahoensis* collected in the Kootenai River Gorge, Lincoln Co., Montana, USA, on 30 May 1985. A radiograph of the individual (Fig. 1) reveals that trunk and anterior caudal vertebrae were affected. Opacities more dense than bone also appear in the trunk and may represent ingested mineral.

A comparison with cleared and stained *P. idahoensis* specimens indicates that this abnormal salamander's SVL would have exceeded 5 cm if not for the unusual spine curvature. The individual was therefore at least 4 yrs old when collected (Lynch 1984. Reproductive Ecology of *Plethodon idahoensis*. M.S. Thesis, University of Idaho, Moscow). Thanks to Chris Davitt for the radiograph and Dan Bivens for photography.

ANURA

BUFO SPECIOSUS (Texas Toad). **DIET.** Reports of food items for *Bufo speciosus* are nonexistent. However, like other xeric toad species, it is presumed to feed on a diverse array of terrestrial and flying arthropods (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.) On 7 August 1998 at ca. 0100 h, a subadult (54 mm SUL, 18.5

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 20, Number 1 (March 1999).

CAUDATA

AMBYSTOMA GRACILE (Northwestern Salamander). **PREDATION** and **CANNIBALISM**. Lack of information concerning predatory interactions between *Ambystoma gracile* and *Ambystoma macrodactylum* (long-toed salamander) larvae, as well as potential cannibalism within *A. gracile* populations, prompted us to conduct a field experiment to investigate the potential for this inter- and intraspecific predation. This field experiment was conducted at a lake in Mount Rainier National Park, Washington, USA.

The experiment, consisting of two trials, was conducted during August 1998. In the first trial, six *A. gracile* larvae (58–94 mm SVL) were collected from lake LW24, and one larva was placed into each of six 11.3 L plastic containers filled with 8 L of water from the lake. Five *A. macrodactylum* hatchlings (10–15 mm TL), which emerged from eggs collected from a pond (UK01) ca. 0.5 miles from the lake, were added to each of the six containers. Ten hatchlings were added to a seventh container, which held no *A. gracile* larva, and this container was used as a control. All hatchlings were added to each container immediately after the addition of the *A. gracile* larvae to the containers. Container lids were secured and the containers were placed under trees on the ground near the lake. Each container was checked ca. five hours after the trial began, and the following morning, for surviving hatchlings. The second trial was conducted the same as the first trial, except that *A. gracile* hatchlings (10–15 mm TL) which emerged from two egg masses collected from lake LW24 were placed into the containers. Six new *A. gracile* larvae (56–80 mm SVL) collected from the lake were used in the second trial.

The results of this experiment indicate that *A. gracile* larvae, when given the opportunity, will prey on *A. macrodactylum* hatchlings and cannibalize conspecific hatchlings. In the first trial, all of the *A. gracile* larvae consumed the *A. macrodactylum* hatchlings. Within ca. five hours from the beginning of this trial, 29 of 30 hatchlings in the six containers had been consumed and the one remaining hatchling was consumed by the following morning. All *A. macrodactylum* hatchlings in the control container were alive the following morning. In the second trial, *A. gracile* larvae also consumed the *A. gracile* hatchlings. Within a little over five hours from the beginning of this trial, *A. gracile* larvae (62–80 mm SVL) in three of the containers had consumed all but one of the hatchlings (i.e., 14 of 15 hatchlings), while 14 of 15 hatchlings still survived in the three containers with smaller larvae (56–60 mm SVL). By the following morning, the last remaining *A. gracile* hatchling in one of the containers with a 62–80 mm SVL larva had been consumed, eight hatchlings were still alive in the containers with the smaller larvae, and all hatchlings in the control container were alive. Survival of the eight *A. gracile* hatchlings in the containers with smaller larvae indicates that the rate of consumption of *A. gracile* hatchlings may, in part, be related to larval size.

AMBYSTOMA RIVULARE (Michoacan Stream Siredon). **CANNIBALISM.** Instances of cannibalism have been well studied in larval *Ambystoma* (Pfennig et al. 1994. Behav. Ecol. 5:225–232; Walls et al. 1993. Oecologia 96:162–168; Wildy et al. 1998. J. Herpetol. 32:286–289). Here we report an observation of larval cannibalism in another ambystomid, *Ambystoma rivulare*, an endemic of the Transvolcanic Belt of México. On 24 August 1991, while censusing a population of these salamanders in a water canal near Buenavista (State of México, km 19 Highway Toluca-Valle de Bravo, 3100 m elevation), we placed two small larvae (20 mm SVL) in a container with two large larvae (55 and 57 mm SVL) to hold them until measured and released. Within 10 min, the small larvae had been eaten. Although the cannibalism took place in an artificial and confined space, our observation points out that cannibalism could occur naturally. It is interesting to note that in the canal, ≤ 20 mm SVL larvae were only found in areas where large larvae (> 20 mm SVL) were absent. Thus, cannibalism in this population may be driving spatial segregation of larval size classes.

SMITH**, Department of Biology, William Jewell College, Liberty, Missouri 64068, USA.

AMBYSTOMA TIGRINUM STEBBINSI (Sonoran Tiger Salamander). **PREDATION.** The federally endangered Sonoran tiger salamander is only known from within 31 km of Lochiel, Santa Cruz County, Arizona, USA (U.S. Fish and Wildlife Service 1997. Fed. Register 62:665–689). Little is known about its natural predators. On 19 July 1997, two adult turkey vultures (*Cathartes aura*) were observed feeding on larval or adult tiger salamanders at the edge of a rapidly drying pool with much of the remaining water confined to cattle hoof prints. The pool, a rainfall run-off catchment was located at 1450 m in the San Rafael Valley ca. 2 km north of the USA-Mexico border at Lochiel in a tributary to the nearby upper Santa Cruz River.

Using binoculars and a spotting scope from a distance of ca. 100 m, I observed vultures feeding on the salamanders. It is unknown if the vultures detected the salamanders from the air or if they took advantage of the opportunity when the came to the tank for water.

Submitted by **RUSSELL B. DUNCAN**, 7441 Calle Maicoba, Tucson, Arizona 85710, USA.

ANEIDES FERREUS (Clouded Salamander). **HABITAT.** *Aneides ferreus* is typically described as an inhabitant of Douglas-fir, redwood, cedar, and alder forests over its range (Bury and Martin 1973. J. Herpetol. 7:331–335; Stebbins 1985. Field Guide to Western Reptiles and Amphibians, Houghton Mifflin Co., Boston, Massachusetts. 336 pp.; Whitaker et al. 1986. Great Basin Natur. 46:228–240). Habitat studies reveal that *A. ferreus* utilizes stands of various age classes, ranging from old growth to young stands (Stemlock and Harestad 1979. Syesis 12:71–75), and is primarily found in rotting logs and stumps, within loose bark and underneath coarse, woody debris on the forest floor (Bury and Corn 1988. USDA For. Serv. Gen. Tech. Rep. RM-166, pp. 11–22; Harestad and Stemlock 1983. Syesis 16:39–41). Anecdotal accounts of arboreality indicate that the species may also utilize canopy epiphytes as habitat (Welsh

and Wilson 1995. Herpetol. Rev. 26:196–197). Furthermore, *A. ferreus* has been found within rocky substrates near road banks and forest clearings (McKenzie and Storm 1970. Herpetologica 46:228–240).

Though most studies were conducted in or around forests, few mention *A. ferreus* utilizing urban landscapes as habitat. McKenzie and Storm (*op. cit.*) collected *A. ferreus* "from under boards, concrete, and litter," in what they termed an "urban backyard," but did not elaborate. Here, we document the presence of *A. ferreus* in an urban environment at a home built in 1895 in Arcata, California, USA (40°52'23"N, 124°05'04"W). The home is bordered on the west and south by frequently traveled, paved roads, on the north by a paved alleyway, and on the east by a vacant church, which is next to an active gas station. The nearest area of "natural" habitat (i.e., second and third growth redwood forest) exists ca. 0.80 km to the east, but is separated from the house by roads, homes, and a freeway trough.

The following observations were made from October 1997 through March 1998, between 1900 and 2300 h. Seven individuals representing three age classes (Whitaker et al., *op. cit.*) were observed. All age classes were observed in flowerbeds or beneath wooden planter boxes within ca. 1.2 m of the house. Adults were also found within the deteriorated masonry lining the base of the house. Salamanders were most frequently observed following bouts of rain, fog, or watering of the surrounding yard. Repeated observations of salamanders occurred in three separate areas. These areas were separated by ca. 3 m and occupied different aspects of the site. Although no feeding was observed, each activity area contained a conspicuous invertebrate food source, consisting of spiders, ants, and sowbugs (Whitaker et al. *op. cit.*; Storm and Aller 1947. Herpetologica 4:59–60).

No eggs were found, but the presence of several age classes suggests that *A. ferreus* is reproducing on site. *Aneides ferreus* occurrence in this urban environment leads to questions regarding their origin at this location and the levels of development which affect their survival. This area was redwood forest prior to the establishment of the township in the latter half of the 19th century, thus it is possible that these salamanders represent a population that has survived the transformation of the landscape. Alternatively, they might represent recent colonization from a nearby population in the neighborhood. Given the apparent insurmountable barriers that exist between the house and redwood forest, it is unlikely that *A. ferreus* migrated to this area recently from its "natural" habitat. These observations suggests that microsite characteristics may be more relevant than macrohabitat characteristics as determining factors of *A. ferreus* presence. Moreover, this account provides additional habitat information regarding a species commonly thought to be a specialist (Welsh and Lind 1988. USDA For. Serv. Gen. Tech. Rep. RM-166, pp. 439–455) in forested areas.

We thank Ken Cullings, V. Tom Parker, and Thomas D. Hovie for their helpful suggestions in preparing the manuscript.

PLETHODON CINEREUS (Red-backed Salamander). **HABITAT**. While studying invertebrate inhabitants of leaves of the bog-dwelling purple pitcher plant, *Sarracenia purpurea*, we discovered two dead *Plethodon cinereus*. The first was recovered in September 1996, at Big Run Bog in the Monongahela National Forest, Tucker County, West Virginia, USA (30°07'N, 79°35'W), when the tube being used to suction the liquid contents from the leaves became clogged with a dead salamander. The second was found on 24 March 1997 at Christner Bog in Mount Davis State Forest, Somerset County, Pennsylvania, USA (40°43'N, 70°11'W). This individual was found wedged tightly into the leaf stem, facing head down. These specimens were catalogued into the Howard University Museum Collection as HUMC 550 (73 mm TL) and HUMC 551 (57 mm TL).

The stomach contents of each salamander were analyzed. Although the stomach of the Christner Bog specimen was empty, the leaf from which it was recovered contained 85 midge larvae (Chironomidae). The stomach of the Big Run Bog specimen held eleven ants (*Myrmica* sp.) and one midge larva. The leaf in which this salamander was found contained 59 midge larvae, six ants (*Myrmica* sp.), one spider (Araneae), ten mites (Acari), seven small beetles (Coleoptera), and seven small wasps (Hymenoptera).

The extent to which *P. cinereus* forages in bogs remains to be documented. Why or how these salamanders died in the leaves is unknown. However, pitcher plant leaves provide a rich food source including dead insects and larvae of several inquilines that feed on dead prey or microorganisms associated with the leaves. The inquilines include the midge, *Metriocnemus knabi*, and the mosquito, *Wyeomyia smithii* (Rymal and Folkerts 1982. J. Alabama Acad. Sci. 53:131–149).

We thank David Smith, Systematic Entomology Laboratory, USDA-ARS, Washington, D.C., for determination of the ants. We thank Forest Service personnel and Peter Rush for their support and Martin Mackenzie for helping with the collections.

PLETHODON HOFFMANI (Valley and Ridge Salamander). **PREDATION**. On 28 April 1998, I collected a northern ringneck snake, *Diadophis punctatus edwardsii*, (24.5 cm SVL; 6.5 cm tail) in Fulton County, Pennsylvania, USA (40°02'00"N, 77°59'05"W) that regurgitated a partially digested *P. hoffmani*. These specimens are catalogued as USNM 531134 (*D. punctatus*) and USNM 531135 (*P. hoffmani*) in the U.S. National Museum.

Although it is known that small salamanders are a common prey of *Diadophis* (Cupp 1994. Anim. Behav. 48:232–235; Lancaster and Wise 1996. Herpetologica 52:98–108), no published reports of predation on *P. hoffmani* exist (Petranka 1998. Salamanders of the United States and Canada, Smithsonian Institution Press, Washington. 587 pp.). *Plethodon cinereus* has been found to comprise a significant proportion of the diet of *D. punctatus* (Blanchard et al. 1979. J. Herpetol. 13:377–402). Because *D. punctatus* occurs at geographic localities inhabited by *P. hoffmani* but not *P. cinereus* (unpubl. data), it seems likely that *D. punctatus* is an important predator of *P. hoffmani*.

RHYACOTRITON VARIEGATUS (Southern Torrent Salamander). **NEST SITE.** The reproductive ecology of *R. variegatus* remains poorly known. Here I report the first *R. variegatus* nest from Cali-

fornia with information on oviposition and development timing. On 28 September 1995, a *R. variegatus* nest was found in McDonald Creek drainage ca. 10 km S of Orick, Humboldt County, California, USA. The nest was discovered in a stream riffle ca. 30 m above a road culvert. An adult male *R. variegatus* was found with the eggs beneath the boulder. The nest site occurred in a 1st-order stream on managed forestland. The stream had a NW aspect with 12% gradient and was 0.5 m wide. Large cobble characterized the substrate, and woody debris was abundant within and near the stream channel. Overstory vegetation was primarily 50–70 year-old coast redwood (*Sequoia sempervirens*), Douglas-fir (*Pseudotsuga menziesii*), and grand fir (*Abies grandis*), with 97% canopy closure.

The clutch consisted of 11 large (mean diameter = 5.6 mm, SD = 0.39, exclusive of jelly layers), cream-colored eggs, deposited singly beneath a small boulder (28 cm x 20 cm) near the center of the stream channel. One egg was lost in the current when the site was disturbed. Ten remaining eggs were placed in a small perforated plastic container, submerged near the location of the original nest site, and anchored in the stream with rebar and large boulders. When possible, the site was visited weekly. The eggs were checked with a hand lens, but embryological development was difficult to document due to the location of the nest and poor lighting conditions. The forelimbs began developing before the hindlimbs, with forelimbs first obvious at 110 days after discovery and hindlimbs at 120 days, external gills were first visible at 132 days. Two eggs decomposed within the first two months of observation and were removed from the container. Seven of the eight eggs in the container hatched between 9 April and 15 May 1996 (193–229 days after discovery), and the last egg hatched between 15 May and 13 June 1996.

Although it is unknown if any predation of eggs occurred before their discovery, the clutch size (N = 11) is similar to that reported for *Rhyacotriton* spp. in Oregon and Washington. A *R. variegatus* nest found in Tillamook County, Oregon contained 34 eggs and likely contained three clutches (mean = 11.3 eggs per clutch) (Nussbaum 1969. Herpetologica 25:277–278). Nussbaum (*op. cit.*) discovered a nest of the Columbia torrent salamander (*R. kezeri)* in Wahkiakum County, Washington which contained 75 eggs and determined the eggs were laid by at least 8 females (mean = 9.4 eggs per clutch). Oviposition timing was estimated as mid-August for the Washington clutch and late October or early November for the Oregon clutch. No embryological development was evident when the California clutch was found, suggesting that oviposition occurred in mid- to late September.

Although a male *R. variegatus* was found beneath the rock at the nest site, I believe the salamander's presence was coincidental. Parental care in *R. variegatus* is unlikely due to the relatively long incubation period of the ova. Additionally, the small size of *R. variegatus* compared to a potential predator, the Pacific giant salamander (*Dicamptodon tenebrosus*), would limit the species' ability to defend nests.

The location of the California nest site is probably not typical for *Rhyacotriton* spp. The two nests described by Nussbaum (*op.cit.*) were communal nests found in the wetted cracks of sandstone, while the California nest was in the middle of the stream channel. Winter storms during the subsequent year altered the stream channel considerably, and boulders of the size covering the nest were moved in the storms. A nest located in mid-stream, like the California nest, would have been disturbed, and the eggs washed downstream.

SALAMANDRA SALAMANDRA (Fire Salamander). **PREDATION**. *Salamandra salamandra* is the most common terrestrial salamander in Europe. Its aposematic black-yellow pattern is associated with skin serous glands (Klewen 1991. Die Landsalamander, Tel 1. Ziemsen Verlag) which may produce serious toxic syndrome in occasional predators (Saracini 1981. Proc. Congr. Hispano-Francés de Herpetología. Jaca. Spain). Unlike other amphibians, this species remains almost completely absent from the diets of both carnivorous and omnivorous mammals. Here we report the predation of *S. salamandra* by an omnivorous ungulate, the wild boar (*Sus scrofa*).

An extensive study of the diet of the wild boar was carried out in the Montseny massif (NE Iberia, UTM 31T DG31), an area dominated by humid Submediterranean forest. The stomach contents of 53 wild boar (30 females and 23 males) obtained from hunting (1986–1990) were analyzed. Prey items were dried, identified under a binocular lens, and weighed. Although the diet was mainly vegetarian (96% dry mass), vertebrates appeared in 45% of contents and represented 2.13% of the biomass (Rosell 1998. Ph.D. Diss. Barcelona University). *Salamandra salamandra* was the only amphibian consumed, appearing in six stomachs (11%, 0.14% dry mass). One of them contained remains (skin and limbs) of three adult salamanders, the other five contained only one salamander each. Both male and female boars 1-4 years of age consumed salamanders (Rosell, unpubl. data) and lacked symptoms of poisoning.

Wild boar foraging involves moving rubbish, stones, and fallen trunks used as refugia by *S. salamandra*. Prey captured in such a way are usually animals which constitute a proportion (ca. 5% biomass consumed) that remains stable between individuals and populations (Massei et al. 1996. Acta Theriol. 41:307–320; Tucak 1996. Zeitschrift für Jadwissenschaft 42:165–172; Taylor and Hellgren 1997. Southwest. Nat. 42:33–39). Some anurans and the urodele *Pleurodeles waltl* were found in the diet of the wild boar population at Doñana, southwestern Spain (Garzón et al. 1984. II Reunión Iberoamericana Cons. Zool. Vert., pp. 466–475). Moreover, unidentified American salamanders were eaten by European feral hogs in the Great Smoky Mountains, USA (Scott and Pelton 1975. Proc. 29th Annual Conf. Southeast. Assoc. Game and Fish Comm., pp. 585–593). However, to our knowledge this is the first report of predation on *S. salamandra* by *Sus scrofa* although both species share most of their ranges in Europe.

Both consumption by several predators and repeated predation by the same individual rule out accidental ingestion with other prey. In NE Iberia, *S. salamandra* is especially abundant in humid forest areas such as Montesny (Llorente et al. 1995. Atlas dels Amfibis and Reptiles de Catalunya i Andorra. El Brau. Figures. Spain). Apparently, skin toxicity does not protect *S. salamandra* from predation by wild boar in such conditions. Alternatively, wild boars could be exploiting carrion of road-killed salamanders, which are observed active in large numbers after rain in some parts of the study area (pers. obs.). This is unlikely, at least in this case, because the wild boars were killed in sectors with few roads and low traffic density. Although salamander contribution to the diet of this ungulate is low, this may have been one of the main causes of mortality for adult *S. salamandra*. It is also noteworthy that some adult *S. salamandra* have been found in Montseny killed, but not ingested, by the American mink (*Mustela vison*), an accidentally introduced species (Arrizabalaga, pers. comm.).

SIREN LACERTINA (Greater Siren). **PARASITISM**. *Siren lacertina* commonly inhabits shallow freshwater environments in the Coastal Plain from Washington, D.C. south to southern Alabama (Wilson 1995. Land Manager's Guide to the Amphibians and Reptiles of the South. Nature Conservancy Press. Chapel Hill, North Carolina. 324 pp.). Such habitats also support a wide variety of copepod species including parasitic forms like *Achtheres micropteri* (Pennak 1953. Freshwater Invertebrates of the United States. Ronald Press. New York, New York. 769 pp.). On 16 October 1995, a large *S. lacertina* was captured at Basin Road Pond (32°01'N, 81°14'W) in Chatham County, Georgia, USA. The specimen was housed at the Savannah Science Museum where museum curators found seven *A. micropteri* with their distal ends embedded within the gill region along the right side of the siren. The aquarium was immediately treated with a combination of sodium chloride, dimethyl (2.2.2.-tricholor-1-hydroxyethyl) phosphonate, and carmoisine B.A. to combat the parasite infection. Removal of the parasites and subsequent treatments of the tank appeared to have eliminated all signs of *A. micropteri*. On 18 December 1995, the siren developed a recurrence of the *A. micropteri* infection. Thirty-nine *A. micropteri* were removed from the body of the siren and preserved in 95% isopropyl alcohol. Twenty-six more *A. micropteri* were left attached and preserved with the siren. The preserved specimen was donated to Armstrong Atlantic State University in Savannah, Georgia as an educational specimen. Additionally, two *Necturus m. maculosus*, housed in neighboring aquaria developed massive *A. micropteri* infections which killed both specimens. It is presumed the *N. maculosus* were infected due to improper sterilization of the lab equipment used to clean the aquaria.

ANURA

BUFO BOREAS (Boreal Toad). **PHORETIC HOST**. Several reports describe amphibians serving as phoretic hosts for sphaeriid bivalves. In most cases the clams attach to the feet of the amphibian, but in one case a *Pisidium* was attached to the lower jaw of a newt (Rees 1952. British J. Herpetol. 1:125–129). Kwet (1995. Salamandra 31:61–64) observed male *Bufo bufo* with *Sphaerium corneum* attached to the distal end of toes on the hind feet.

Here we report phoretic attachment of *Pisidium* sp. to recently metamorphosed *Bufo boreas*. In 1996 and 1997 ca. 24,000 hatchery reared *B. boreas* toadlets were reintroduced to Lost Lake, Boulder County, Colorado, USA. In 1997, the site was surveyed ca. three times per week between 3 June and 18 August. During the survey on 4 Aug 1997, two of 303 (0.7%) recently metamorphosed toadlets were found with *Pisidium* sp. attached. Both toadlets were on a muddy surface and had the clam attached to the distal end of a toe on the rear foot. The specific identity of the clams is unknown, as at least three species of *Pisidium* (*P. milium*, *P. nitidum*, and *P. variabile*) have been reported from Lost Lake (Wu 1989. Colorado Freshwater Mollusks. Nat. Hist. Inventory of Colorado. 11. Univ. Colo. Museum, Boulder).

Relatively few accounts of phoretic attachment by sphaeriid bivalves mention the season, but of those that do, most attachments appear to occur in the spring. Spencer (1964. J. Colorado-Wyoming Acad. Sci. 5:43–44) observed *Pseudacris triseriata* throughout their activity season, but only observed phoretic attachment by *Pisidium* during May. Our observations demonstrate that phoretic attachment also occurs during late summer.

HYLA FABER (Smith Frog). **LARVAL CANNIBALISM**. Martins (1993. Amphibia-Reptilia 14:411–421) observed that during droughts most *Hyla faber* tadpoles occurring in high densities in the foam nests had their tail tips mutilated, probably by their siblings. During the nights of 25 April and 27 June 1998, in a permanent pond (2 x 3 m) at Guarani River margin, Três Barras do Paraná County, Paraná State, Brazil, we found two dead *H. faber* tadpoles (ca. 65 mm TL; stage 25, Gosner 1960. Herpetologica 16:183–190) being consumed by four tadpoles of the same species and similar size. Although cannibalism in tadpoles of the *H. boans* group is known for *H. rosenbergi* (Kluge 1981. Misc. Publ. Mus. Zool. Univ. Michigan 160:1–170), this is the first report of cannibalism in *H. faber* tadpoles. The tadpoles were verified by A. A. Giaretta and deposited at Museu de História Natural da Universidade Estadual de Campinas (ZUEC 11546–548), Campinas, SP, Brazil.

LITORIA LESUEURI (Stony Creek Frog). **PREDATION**. Eels are generally known to prey upon invertebrates, fish, and crustaceans (Allen 1989. Freshwater Fishes of Australia. T.F.H. Publications, Neptune, New Jersey. pp. 24–26) and are ubiquitous throughout streams of eastern Australia. In southern Australia a number of unidentified adult frogs were encountered in the diet of short-finned eels (*Anguilla australis*) (Beumer 1979. J. Fish Biol. 14:573–592); but no frogs were found in the diet of sympatric long-finned eels (*A. reinhardtii*). The impact of long-finned eels on anuran assemblage structure in the streams of eastern Australia, where short-finned eels are absent, is unknown.

During a routine survey at Cedar Creek Falls in southeastern Queensland (27°53'40.6"S 153°11'16.2"E), predation by a long-finned eel on an adult frog was observed. At ca. 1930 h on the 23 October 1998, a male *Litoria lesueuri* jumped from the bank into the stream, landing above a long-finned eel partially hidden among aquatic vegetation. The eel immediately seized the frog and only the hind legs were seen protruding from the eel's mouth. Within seconds, a second bite ensured the frog was swallowed entirely. The eel showed no signs of rejection and continued its foraging activity. Interestingly, tadpoles of *L. lesueuri* are toxic or distasteful to fish predators (J.-M. Hero, unpubl. data), while this observation suggests that adult *L. lesueuri* are not distasteful to vertebrate fish predators. Furthermore, this observation suggests that long-

finned eels may be important predators on adult amphibians in freshwater systems of eastern Australia.

Submitted by **MATHEW ADRIAN HARVEY, CLARE MORRISON,** and **JEAN-MARC HERO**, School of Environmental & Applied Science, Griffith University Gold Coast, PMB 50 Gold Coast MC, Queensland 9726 Australia (e-mail: M.Hero@mailbox.gu.edu.au).

RANA LUTEIVENTRIS (Columbia Spotted Frog). **MORTALITY and SITE FIDELITY.** Ranid frogs primarily occupy permanent wetlands. That they persist in desert streams that expand and contract greatly (Stanley et al. 1997. BioScience 47:427) is remarkable. While several species of ranids aestivate to cope with surface climate conditions beyond their limits of physiological tolerance (Pinder et al. 1992 *In* Feder and Burggren (eds.)., Environmental Physiology of the Amphibians, pp. 250–274. Univ. Chicago Press, Chicago), our observations indicate that *Rana luteiventris* at the southernmost extent of its range has not evolved such behavior.

On 14 July 1997, we observed three dead frogs (1 J, 1 M, 1 F), four living frogs (1 J, 2 M, 1 F), and 15 tadpoles (water 29°C; Gosner stage 43–44; Gosner 1960. Herpetologica 16:183–190) at an elevation of 1745 m along a 150 m intermittent portion of Cloverdale Creek, Nye County, Nevada, USA (T8N R39E NW1/4 Sec. 13; air 32°C). This site is heavily used by livestock as evinced by a mean of 13.3 (SD = 2.55) livestock hoof prints per m^2.

The three dead frogs were above ground in awkward postures that suggested traumatic deaths. One adult male was thin (60 mm SUL; 12 g [the mean weight of seven other 60 mm males from nearby areas was 20.9 g, SD =1.87]) and lethargic and possessed a partially everted bladder. Of the living frogs, one adult male and one juvenile were observed in two small (2.0 m x 1 m) pools ca. 5 cm in depth. The adult female was observed ca. 75 m up the dry creek bed, partially hidden in the moist soil of a cow hoof print. One of the adult males emerged from water-saturated clay substrate during the survey. We PIT tagged all living *R. luteiventris* > 45 mm SUL.

We revisited this site on 23 July 1997 (water temp: 25.5°C; raining steadily during survey) and observed one dead adult male with a crushed backbone and broken left rear foot in the impression of a cow hoof. We located two live adult frogs on moist soil in the dry creek bed. One frog was observed in the open, the other partially hidden in a cow hoof print. Both frogs were implanted with PIT tags.

We returned to the site on 23 July 1997 and found two dead adult frogs (one desiccated, other recently dead) and one live adult male. Eight net sweeps of the two pools did not reveal the presence of tadpoles.

On 28 July 1997 (overcast; air temp 16.5°C), we surveyed the transect, now devoid of pooled water, and located three adult males and one juvenile. The first adult and the subadult were hidden under rocks (0.3–0.7 m diam) embedded in the creek bed. The second was moving up the dry creek bed. The final adult male was recaptured beneath a boulder, 40 m upstream from where it was marked on 23 July 1997.

In North American arid systems, due to a variety of anthropogenic impacts and natural desertification, many streams are in the process of drying and now have intermittent flow patterns. Amphibians that depend on permanent water systems are increasingly at risk because they lack the behavioral mechanisms to cope with the new stochastic nature of their aquatic habitats. While long-range dispersal has been documented in this system in "wet years" (Reaser 1996, Herpetol. Rev. 27:196), the rapid loss of water from a stream may not enable emigration of all frogs. At this site, the presence of desiccated algal mats along the dry streambed indicated that stream flow extended an additional km downstream earlier in the season. Sparse clumps of dried filamentous algae, and water pennywort (*Hydrocotyle* sp.) remained on moist soil, indicating that pooled water had also been present. At the time of the surveys, the nearest pooled water existed ca.1 km upstream from the transect.

The majority of dispersal data for this system (Reaser, in prep.), however, indicate that site fidelity (Sinsch 1990. Ethol. Ecol. Evol. 2:65) is extremely high. A low propensity to emigrate would further exacerbate vulnerability of frogs that don't have successful physiological means to cope with rapid climate shift.

These observations illustrate the presence of declining habitat at the southernmost location known for the species (Green et al. 1996. Evolution 50:375). As a result of rapid stream retreat, frogs concentrate in pools and are vulnerable to mortality due to dehydration and livestock trampling. Additionally, observations such as these have led resource managers and users in the region to consider alternatives to intensive livestock grazing. Under a conservation agreement for *R. luteiventris* in the Toiyabe Range (in progress), the U.S. Forest Service (USFS) and the Yomba Shoshone Tribe will be fencing livestock out of sensitive wetlands. Further, the USFS has acquired previously ranched lands and no longer grants grazing permits in certain riparian areas.

These observations were made as part of a four-year study of the conservation ecology of *R. luteiventris* in Nevada. We thank the USFS (Tonopah Ranger District) for logistical support, the U.S. Bureau of Land Management for allowing access to their lands, and Nevada Division of Wildlife for the necessary permits. Funding was provided to JKR by the Nevada Biodiversity Initiative, Doctoral Research Fellowship of Stanford University, U.S. Fish and Wildlife Service, National Fish and Wildlife Foundation, Nevada Mining Association, IUCN Declining Amphibian Task Force, Theodore Roosevelt Memorial Fund, and Morrison Institute for Population and Resource Studies. We thank C. R. Peterson and D. S. Pilliod for constructive comments on this note.

RANA MUSCOSA (Mountain Yellow-legged Frog). **DIET**. On three occasions during August 1997, I observed adult *Rana muscosa* consuming *Hyla regilla* tadpoles. The events occurred in water <5 cm deep in two ponds <0.2 ha in upper Dusy Basin, Kings Canyon National Park, California, USA. On all occasions, the *R. muscosa* were basking in warm, shallow water (>18°C) surrounded by numerous *H. regilla* tadpoles. In the shallow regions of the pond at mid-day, there were 15 adult *R. muscosa* and ca. 1500 *H. regilla* tadpoles within a 2 m^2 area. Occasionally a *H. regilla* tadpole passed in front of an adult *R. muscosa,* which would lunge at the tadpole open-mouthed. When successful, the frog would swallow the tadpole head first. On another occasion an adult *R. muscosa* was captured with a *H. regilla* tadpole tail protruding from its mouth. Tom Jenkins (pers. comm.) observed *R. muscosa* feeding on *H. regilla* tadpoles in a pond in the Mills Creek drainage, John Muir Wilder-

ness in August 1996. Thus this behavior is not restricted to the population of *R. muscosa* at the Dusy Basin site. This is the first reported case of *R. muscosa* feeding on *H. regilla* tadpoles.

RANA SYLVATICA (Wood Frog). **PREDATION**. Anurans and waterstriders (Insecta: Hemiptera: Gerridae) often co-exist in small ponds, where waterstriders may represent a significant prey item for adult anurans (Callahan 1974. Proc. Entomol. Soc. Washington 76:15–21). Here we report predation on *Rana sylvatica* larvae by waterstriders. On 28 May 1998, we observed ca. 78 *R. sylvatica* larvae trapped in a small pool (25 x 14 cm; max. depth 2 cm), all that remained of a drying pond (ca. 55°11'45"N, 113°39'30"N). On 13 May this pond had been 17 x 14 m, with a max. depth of 20.5 cm. Ten *R. sylvatica* egg masses had been found in the pond at that time. The pond was located in a cutblock logged in winter 1996/97, in the aspen (*Populus tremuloides*) dominated boreal forest of Alberta, Canada.

The tadpoles trapped in the pool were aggregated in the deeper water in the center. We observed fewer than 20 waterstriders in the immediate area of the pool, with one to five waterstriders feeding on the tadpoles at any given time. We never observed more than one waterstrider feeding on a single tadpole simultaneously. The majority of tadpoles appeared moribund or dead, although several exhibited weak swimming motions, either in the normal orientation or upside-down. We observed waterstriders inserting their rostrum into the portion of the tadpole's body that was closest to the surface of the water, and apparently feeding. Some tadpoles exhibited weak escape responses, trying to swim away, but the attacking waterstriders were able to maintain their position over the tadpole and continue to feed. Individual waterstriders were observed feeding on single tadpoles for up to 5 minutes.

We collected a number of tadpoles and waterstriders at the site. All tadpoles were *R. sylvatica* with small hind limb buds present (mean developmental stage 27.2, SD = 1.85, N = 13) (Gosner 1960. Herpetologica 16:183–190), and a mean body length of 1.79 cm (SD = 0.23, N = 18). Two species of waterstriders were collected: *Gerris pingreensis* (body length 0.65 cm, N = 1), and *G. buenoi* (mean body length = 0.83 cm, SD = 0.042, N = 4). All waterstriders collected were adults; the *G. pingreensis* had fully developed wings, while *G. buenoi* lacked wings, meaning that they would perish as the pond disappeared. Lack of wings in adult waterstriders is common in populations in Alberta (Spence 1989. Can. J. Zool. 76:2432–2447). Waterstriders generally feed on soft-bodied arthropods trapped in the surface film of the water; prey items may be insects blown onto the water from terrestrial habitats, or adults emerging from aquatic larval stages (Andersen 1982. The Semiaquatic Bugs. Entomonograph Vol. 3. Scandianvian Science Press, Ltd., Klampenborg, Denmark). It is unlikely that waterstriders are often able to prey on anuran larvae, as tadpoles generally remain submerged, while waterstriders are usually confined to the surface itself. We have similarly observed aggregations of waterstriders feeding on individual fathead minnows (*Pimephales promelas*) that were floating dead on the surface of ponds (C. Paszkowski, pers. obs.).

This is the first published report of which we are aware that describes waterstriders feeding on anuran larvae, although this phenomenon has been observed previously in the field by entomologists (J. Spence, pers. obs.). Many species of waterstriders are known to be opportunistic unspecialized feeders (Spence and Scudder 1980. Can. Entomol. 112:779–792); our observation of waterstriders feeding on a novel vertebrate prey supports this characterization.

SCAPHIOPUS COUCHII (Couch's Spadefoot). **PREDATION**. Ants have been shown to prey upon juvenile and adult frogs and toads (Clerke and Williamson 1992. Austr. Zool. 28:64–67; Fritz et al. 1981. Biotropica 13:158–159), and eggs of the salamander *Desmognathus ochrophaeus* (Forester 1979. Herpetol. Rev. 10:3–4). The following observation appears to be the first record of ant predation upon anuran eggs.

On 2 July 1998, we observed a group of ants (*Forelius mccooki*) (2.2 mm TL) eating *Scaphiopus couchii* eggs. The eggs were attached to a blade of grass suspended into the water at the edge of an ephemeral pool located in Big Bend National Park, Brewster Co., Texas, USA (UTM zone 13, 3256531N, 0680510E, 843 m elev., air 35.3°C, water 33.6°C, relative humidity 49%, pool ca. 3.5 m x 3.0 m x 0.50 m deep). The eggs were viable and had been laid ca. 12–15 h earlier. The ants walked along the blade of grass and onto the top of the gelatin of the egg mass on the water surface. Approximately 100 ants had eaten through the gelatinous envelope of the eggs (10% of egg mass) and were harvesting the ovum and returning to their nest.

Forelius mccooki typically forage on live and dead insects as well as tend honeydew-excreting insects (Wheeler and Wheeler 1986. The Ants of Nevada. Natural History Museum of Los Angeles County, Los Angeles, California. 138 pp.). Collected ants were deposited in the collection of the Department of Entomology of the National Museum of Natural History.

We thank A. F. Van Pelt and Ted R. Schultz for identifying *Forelius mccooki* and Raymond Skiles at Big Bend National Park for the tremendous amount of help he has given us. This study is part of DISPro (the Demonstration Intensive Site Program), a joint index site and ecological research program funded by the U.S. Environmental Protection Agency and National Park Service.

TESTUDINES

CHELUS FIMBRIATUS (Matamata). **MAXIMUM SIZE**. The maximum straight-line carapace length (CL) of *Chelus fimbriatus* reported by Pritchard and Trebbau (1984. Turtles of Venezuela. SSAR Contributions to Herpetology, No. 2. 403 pp.) is 456 mm. Sánchez Villagra et al. (1995. Chel. Cons. Biol. 1:293–300) reported a matamata with a CL of 464 mm. A *C. fimbriatus* captured by local fishermen in the vicinity of Puerto Ayacucho, Departamento Atures, Estado Amazonas, Venezuela had a CL of 482 mm. Other measurements (all straight-line) include: 430 mm plastron length; 380 mm carapace width; 170 mm shell height. This specimen was deposited in the collection of the Estación Biológica Rancho Grande, Maracay (EBRG 3596). We believe this is the largest *C. fimbriatus* ever reported in the literature.

DERMOCHELYS CORIACEA (Leatherback Sea Turtle), ***LEPIDOCHELYS KEMPI*** (Kemp's Ridley Sea Turtle), and ***CARETTA CARETTA*** (Loggerhead Sea Turtle). **PELAGIC FEEDING.** Hendrickson (1980. Am. Zool. 20:597–608) discussed differences in the niches occupied by extant sea turtles. However, other studies have reported a high degree of dietary overlap among *Lepidochelys kempi, Caretta caretta,* and *Dermochelys coriacea* (Grant and Ferrell 1993. Brimleyana 19:77; Frick 1997. Herpetol. Rev. 28:149; Frick and Mason 1997. Herpetol. Rev. 29:166–168). Here, we report aerial observations of *D. coriacea*, *L. kempi*, and *C. caretta* feeding together within large flotillas of cannonball jellyfish (*Stomolophus meleagris*), as well as observations of *L. kempi* and *C. caretta* feeding together within large schools of migrating cownose rays (*Rhinoptera bonasus*). To our knowledge, *S. meleagris* and *R. bonasus* have never been reported from the diets of *L. kempi* and *C. caretta*. Additionally, our observations suggest a lack of resource partitioning between *D. coriacea, L. kempi*, and *C. caretta*.

Our observations occurred on 29 and 31 March 1998 (1011–1454 h). Water temperature was 20°C and water depth at feeding locations was 1.8–23.4 m. Our observations were made during aerial surveys conducted by the New England Aquarium along coastal waters from southeastern Georgia (31°17'N, 81°00.0'W) to northeastern Florida (30°14'N, 81°05.0'W). For more detailed information regarding similar surveys see Scott and Gilbert (1982. U.S. Dept. Interior Rep. AA551-CT8-48. 120 pp.) and Knowlton et al. (1994. Can. J. Zool. 72:1297–1305.).

During the spring, large, surface-active schools of cownose rays begin to migrate north through the coastal waters off Georgia and Florida (R. Kenney, unpubl. data). Schools of cownose rays can number up to 30,000 individuals. However, schools of 200–300 individuals are more common. Similarly, large flotillas of cannonball jellyfish also appear off the coast during much of the year (March–November), until colder weather drives them south.

On 16 separate occasions, 34 *C. caretta* and 4 *L. kempi* were observed feeding on cownose rays. Turtles were observed biting pieces from the wings of any *R. bonasus* that passed within ca. 0.9 m. Large schools of unidentified fish were observed swimming beneath feeding turtles. These fishes appeared to be feeding on injured rays. On 10 separate occasions, 17 *C. caretta* , 2 *D. coriacea*, and 4 *L. kempi* were observed feeding on cannonball jellyfish. Larger turtles appeared to be eating jellyfish whole, whereas smaller turtles appeared to be manipulating jellyfish with their foreflippers, and consuming them as smaller, manageable pieces. On four occasions, ocean sunfish (*Mola mola*) and sharptail molas (*Mola lanceolata*) were seen feeding on jellyfish alongside of turtles.

It is unclear to what extent sea turtles utilize the seasonal influx of potential prey items that migrate through their foraging areas. By combining low energy behavioral activities such as basking and pelagic foraging, sea turtles may attain enough energy to perform activities that require a high energy expenditure. Grant and Ferell (1993, *op. cit.*) suggest that the low-cost benefits associated with simultaneous basking and pelagic feeding may enable leatherbacks to perform more lengthy migrations while following jellyfish, their primary food. Studies that address diet selectivity in sea turtles by relating relative abundance of potential food items in the environment to the food items that are ingested would help us to better understand the foraging ecology of sea turtles (Bjorndal 1997. *In*: Lutz and Musick (eds.), Biology of Sea Turtles, pp. 199–232. CRC Press, Boca Raton, Florida).

NATATOR DEPRESSUS (Flatback Sea Turtle). **PREDATION.** *Natator depressus* hatchlings are up to 1.5 times larger than those of other cheloniids (Limpus 1989. Aust. Wildl. Res. 16:517–525). It has been widely accepted that their large size provides protection from predation by ghost crabs (Walker and Parmenter 1990. J. Biogeogr. 17:275–278).

On 21 June 1998 at 0240 h at a mainland rookery at Fog Bay, Northern Territory, Australia (12°42'S; 130°20'E), SJB discovered a nest where *N. depressus* had recently hatched. The tracks of a ghost crab were seen intercepting the tracks of a hatchling. About 5 m further along the beach, a ghost crab, *Ocypode cordimana* (George and Knott 1965. J. Roy. Soc. W.A. 48:15–21), was carrying a *N. depressus* hatchling by the neck. The crab dropped the hatchling when approached. Although there have been reported sightings of predation on flatback hatchlings by the ghost crab *Ocypode ceratophthalma* (Limpus 1971. Herpetologica 27:431–446), this is the only known report of *O. cordimana* preying on a flatback hatchling.

The hatchling was dead, and had wounds to the neck, like those reported for crab attacks on hatchlings of other species of sea turtles (Bustard 1972. Australian Sea Turtles. Collins, Sons and Comp., London. 220 pp.). SDW has made similar observations on Bare Sand Island, but the crabs involved were not identified. It may be that ghost crab predation on *N. depressus* hatchlings is more prevalent than previous authors have acknowledged.

Our research was funded by National Estates Grants Program, The Queen's Trust for Young Achievers, Australian Geographic, and the Centre for Tropical Wetlands Management (Northern Territory University).

LACERTILIA

BARISIA IMBRICATA IMBRICATA (Popocatepetl, Imbricate Alligator Lizard). **OOPHAGY**. Mitchell and Groves (1993. Herpetol. Rev. 24:126–129) published an excellent review of reports of oophagy in reptiles; herein I report oophagy in captive female *Barisia imbricata imbricata*. Five gravid *B. i. imbricata* females were collected on 1 June 1992 in Cahuacán, State of México, and were maintained in captivity in individual terraria. Within two weeks, parturition occurred in every individual. After the birth of each neonate, the mother tongue-licked it and ate the extraembryonic membranes. Two of these females gave birth to live neonates as well as non-viable eggs and dead neonates. The number of tongue-licks was greater for non-viable products than for live neonates and the females subsequently ate the nonviable eggs and the dead neonates. This behavior suggests that the females distinguish between viable young and non-viable products. Similar behavior has been observed in *Tiliqua rugosa* (Bull et al. 1994. J. Herpetol. 28:117–120), where parents can distinguish their own young from the young of other parents of the same species. It has been proposed that in-

traspecific oophagy is probably a form of parental care. Although several hypotheses have been advanced to explain causes of this behavior in oviparous reptiles, for viviparous reptiles there is no explanation.

I thank Derek Wotton Styles for assistance with the revision of this manuscript.

Submitted by **MARTÍN MARTÍNEZ TORRES**, Laboratorio de Biología de la Reproducción, Escuela National de Estudios Profesionales Iztacala UNAM, Los Reyes Iztacala, A.P. 314, Tlalnepantla Edo. de México C.P. 54090, México.

GALLOTIA ATLANTICA (Atlantic Lizard). **PREDATION.** Shrikes are probably not the most important predators of lizards, but they have developed an innovative way of killing their prey—by impaling them. During the breeding season in Poland, *Lanius collurio* (red-backed shrike) have been observed impaling *Lacerta agilis* (Fiala 1986. Ziva. 34:158). We report here on another instance of the same technique observed on Timanfaya (Lanzarote, Canary Islands). On 24 March 1998, eight individuals of *Gallotia atlantica* were found impaled on the leaves of a palm tree. The bird responsible for this larder was *Lanius excubitor koenigi* (great grey shrike). The lizards were positioned just above the ground and ca. 20 m from a nest containing four young shrikes. Six of the lizards were almost completely eaten, with only the skulls remaining. Of the other two carcasses, one was completely dry, while the other was fresh with the eyes, tail, and part of the abdomen already eaten. These last two individuals had been skewered lengthwise—cloaca to head—on the palm leaves. The size of the lizards (by comparison with preserved specimens) corresponded to that of adults (ca. 70–80 mm SVL). Thus predation on *G. atlantica* by shrikes during the latter's breeding season could be an important factor in the population dynamics of both species. Future field studies are needed to determine whether the grey shrike also impales lizards at other times of the year.

We thank the government, Cabildo of Lanzarote, and the Timanfaya National Park for allowing us to study this lizard (Resolution no. 392/98).

HEMIDACTYLUS BROOKI (Spotted House Gecko). **COMMUNAL BREEDING.** *Hemidactylus brooki* is a common gecko inhabiting households in Dharwad, South India (15°17'N, 75°3'E). It is also found in Sri Lanka, Burma, Indonesia, and the Malaysian and Philippine Islands. In Dharwad, *H. brooki* reproduces from October until June (Shanbhag et al. 1998. J. Herpetol. 32:566–572), producing two eggs per clutch. The eggs are usually deposited on a horizontal surface, hidden from view. On 14 May 1997 I observed 16 *H. brooki* eggs adhering to a wall behind a framed photograph measuring 75 cm x 50 cm. The 16 eggs were deposited in an area of 15 cm x 20 cm, suggesting communal breeding. One group of four were clumped together, eight were deposited in pairs, and the remaining four were attached singly.

Communal deposition of eggs has been reported in the Australian gecko, *Oedura lesueri* (Bustard 1967. Herpetologica 23:276–284), and in *Hemidactylus turcicus* (Flower 1933. Proc. Zool. Soc. London: 735–851., R. K. Vaughan, pers. comm.).

LEPIDODACTYLUS LUGUBRIS (Mourning Gecko). **NECTIVORY and DAYTIME ACTIVITY.** With few exceptions, geckos are nocturnal insectivores. A few species occasionally feed on natural or man-made sweet semi-liquids such as nectar or honey. *Lepidodactylus lugubris* is one such species (Greer 1989. The Biology and Evolution of Australian Lizards. Surrey Beatty & Sons, Hong Kong. 264 pp). McCoid and Hensley (1993. Herpetol. Rev. 24:87–88) suggested *L. lugubris* will regularly change activity patterns to feed on such resources. Here we report on several instances of such behavior and provide statistical support suggesting these were indeed systematic, rather than incidental. We made our observations on the island of Guam. They include chance sightings, when the behavior occurred during the day and involved a large number of individuals, and a small-scale systematic study.

McCoid and Hensley (1993, *op. cit.*) reported that consumption of sweet scraps in households is not unusual. We have also received incidental reports and witnessed additional cases of house-dwelling mourning geckos feeding on jam and sugar crystals. In households where they are not molested, geckos may descend to lick dinner plates clean after a meal (R. D. Anderson, pers. comm.) or feed on ripe fruit left on the kitchen table (C. S. Lobban, pers. comm.). Several people reported encountering them in discarded cans of sweetened drinks (D. S. Vice, pers. comm.; G. J. Wiles, pers. comm.). However, such events are apparently not limited to sweet foods. In one of our households they will sometimes drink milk from meal bowls. Our incidental observations also include sightings of geckos licking what appears to be nectar from the flowers of ornamental orchids and papaya trees (*Carica papaya*).

Our systematic observations were mostly made on the grounds of the Guam National Wildlife Refuge. Like McCoid and Hensley (1993, *op. cit.*), we repeatedly observed *L. lugubris* attracted to the blooms of coconut trees (*Cocos nucifera*). Geckos would lick closed flowers, the drops of clear sweet liquid emanating from them, and the scars where flowers had previously been, as well as open flowers. At times, more than ten individuals of various sizes and color morphs would be engaged in this behavior on a single inflorescence, though on most occasions we only saw a single gecko. On many cases, most recently during September 1998, this behavior occurred during mid-day, both on cloudy and on clear days. The lizards would retreat during the sunniest periods, but seemed nearly oblivious to the presence of observers. They would occasionally engage in agonistic behavior, with individuals apparently fighting over access to the resource. During early September 1998, nearly every flowering tree we could find had at least one *L. lugubris* feeding on nectar during the day. To quantify this behavior we carefully searched 46 short coconut trees. Most either had flowers ($N = 9$) or had wilted flower stalks, often with developing fruit on them ($N = 28$). Of trees with flowers, seven (78%) had active geckos during the day, whereas we observed a gecko on only one (3%) of those without flowers. This difference was highly significant ($p < 0.001$, Fisher's exact test). In two cases we observed an adult *Hemidactylus frenatus* near an inflorescence occupied by a *L. lugubris*. Neither engaged in aggressive behavior, and we saw no indication of a change in *L. lugubris* behavior as a result of this presence.

Mourning geckos would occasionally feed on the many insects, mostly ants and flies, that were also attracted to the flowers. Most

insects were ignored, suggesting that obtaining nectar was the main incentive for this flower-seeking behavior. To further investigate this we also examined 15 flowering ornamental palms (*Veitchia merrillii*). Though most had insects in their inflorescences we saw no liquid on these flowers and found no active geckos on them. Feeding on invertebrates thus appears to be an opportunistic secondary activity. Given the large number of individuals involved in nectar feeding, *L. lugubris* could potentially serve as a pollinator for *Cocos nucifera*, which contains both male and female blossoms. Other species of flowering plants might also benefit from this behavior.

We thank M. J. McCoid for helpful comments on this note.

LEPOSOMA GUIANENSE (NCN). **PREDATION.** *Leposoma guianense* is a small gymnophthalmid lizard reaching ca. 40 mm SVL and a maximum weight of 1.9 g. This diurnal species lives in leaf litter and is often observed preying on small arthropods. The species is very common at the St. Eugène Paris Natural History Field Museum field station (4°51'N, 53°3'W) in French Guiana (Convention EDF-Muséum GP 7531). On 25 April 1997 at 1528 h, on the side of a small lane, a spider was observed biting an adult *L. guianense* on the neck. The lizard was already dead and the spider had begun to eat it head first. Photographs were taken and both specimens were collected and placed in a small box for further identification. Less than 30 min later, only a small piece of the tail remained of the lizard. The spider was identified as a juvenile of the genus *Ctenus* (Ctenidae). This genus has previously been reported to prey on *Anolis nitens chrysolepis* in French Guiana (Massary and Ineich 1997. Rev. Fr. Aquariol. 24:3–4). Ctenid spiders are very common in leaf litter and may play an important role in the regulation of populations of leaf litter lizards.

Submitted by **JEAN-CHRISTOPHE DE MASSARY**, Muséum National d'Histoire Naturelle, Laboratoire de Zoology (Reptiles et Amphibiens), 25 rue Cuvier, F-75005 Paris, France (e-mail: massary@cimrsl.mnhn.fr).

PHRYNOSOMA DITMARSI (Rock Horned Lizard). **TESTIS CYCLE.** The purpose of this note is to report on a histological examination of testes from four *P. ditmarsi* from Sonora, México. Specimens were examined from the herpetology collection of the University of Arizona, Tucson (UAZ) 32357, 32358, 39540, 50565. Mean SVL was 66.8 mm ± 6.1 SD (range = 59–73 mm). Specimens 32357 and 32358 were collected 26 September–8 October 1970, 26–32 km SE of Cananea, 39540 was collected 13 July 1974, 26 km (by road) NE of Baviacora, 50565 was collected 5–6 September 1972, ca. 22 km NE of Baviacora. The left testis, epididymis, and vas deferens were removed and embedded in paraffin for histological examination. Sections were cut at 5 µm and stained with hematoxylin followed by eosin counterstain. Spermiogenesis was in progress in the testes from September–October males. The seminiferous tubules were lined by dense clusters of sperm behind which were several rows of metamorphosing spermatids. Epididymides and vasa deferentia contained sperm. The smallest spermiogenic male measured 59 mm SVL. The testis from the July male was in recrudescence. Primary spermatocytes were the predominant cell. No sperm were present in the epididymis or vas deferens. Lowe and Howard (1975. Southwest. Nat. 20:265–270) reported from sight observations of preserved material that *P. ditmarsi* testes were regressed (minimum activity) in mid-summer and at maximum recrudescence in autumn, suggesting a testis cycle similar to that of *Phrynosoma douglasii*, a late winter, early spring breeder in Arizona (Goldberg 1971. Herpetologica 27:311–314). However, from the above histological observations, male *P. ditmarsi* undergo testicular recrudescence in July and breed during autumn. The testis cycle of *P. ditmarsi* therefore appears similar to that of *Sceloporus jarrovii*, an autumn breeder in Arizona (Goldberg 1971. Herpetologica 27:123–131).

I thank Charles H. Lowe (The University of Arizona) for permission to examine *P. ditmarsi*.

PLACOSOMA GLABELLUM (NCN). **REPRODUCTION.** During sampling of the leaf litter in the Atlantic forest in Ilha de São Sebastião, southeastern Brazil (23°47'S; 45°24'W), we found two clutches belonging to *Placosoma glabellum*. The first clutch consisted of one egg (not measured) collected on 12 January 1998, 300 m elevation. The second clutch consisted of two eggs (11.40 x 8.25 mm, 0.40 g; 11.35 x 8.15 mm, 0.39 g) collected on 25 January 1998, 300 m elevation. The clutches were found ca. 13 km apart. The clutches were kept separately in plastic boxes (13.5 x 13.5 x 4.5 cm), in which they were placed on layers of damp cotton and maintained at air temperatures of 25–29°C. The egg in the first clutch hatched between 17 and 25 February 1998, and the hatchling was not measured. The two eggs of the second clutch hatched between 1 and 3 March 1998. The hatchlings were measured and deposited in the Museu de Zoologia, Universidade de São Paulo, São Paulo, Brazil (MZUSP) (SVL 24.35 mm, tail length 42.40 mm, MZUSP 83479; and SVL 23.35 mm, tail length 43.20 mm, MZUSP 83480). We also collected one adult female *P. glabellum* (SVL 52.90 mm, tail length 73.80 mm, 2.28 g, MZUSP 83478) from the same locality as the second clutch. This female was dissected, revealing two vitellogenic ovarian follicles (one in each ovary) measuring 5.4 x 4.2 mm and 5.8 x 4.3 mm, respectively.

There are no published accounts of reproduction in *P. glabellum*. Our data suggest that the life history strategy of this species is to produce relatively small clutches of relatively large offspring.

We thank A. M. F. Pacheco, G. Machado, and L. dos Anjos for field assistance, O. A. V. Marques for encouragement, laboratory assistance, and suggestions on the manuscript, and M. S. Araújo for suggestions on the manuscript. RJS thanks CAPES (Fundação Coordenação de Aperfeiçoamento de Pessoal de Nível Superior) and RN thanks CNPq (Conselho Nacional de Desenvolvimento Científico e Tecnológico) for research grants.

URANOSCODON SUPERCILIOSUS (NCN). **DIVING.** Our observation was made during an ecological impact study of a hydroelectric power dam on the Sinnamary River in French Guiana (Convention EDF-MusÈum GP 7531). The study area was near the St. Eugène station, a Paris Natural History Museum field station (4°51'N, 53°4'W), ca. 24 km from the dam. On 11 April 1996, we observed a specimen of *Uranoscodon superciliosus* diving, and we were able to time the exact duration of its dive. The specimen, an adult male (145 mm SVL, with a 262 mm regenerated tail) was captured, photographed, measured, and released at 1545 h from a boat ca. 9 m from shore. The specimen dived just in front of us and remained at a depth of ca. 22 cm for 24 min 40 sec. The lizard then emerged for ca. 1 sec, took a single breath, and submerged a second time.

SERPENTES

CONTIA TENUIS (Sharp-tailed Snake). **DEFENSIVE BEHAVIOR.** On four occasions, we observed and photographed seven juvenile *Contia tenuis* in an apparent defensive posture in response to disturbance by observers. When picked up, the snakes coiled into tight balls, with their heads hidden inside their coils, and maintained this position for several minutes. The tail of one snake protruded from the coil in an upright position. On one occasion, two snakes assumed the coiled posture upon exposure when we lifted the cover under which they were sheltered (Fig. 1). All snakes were 78–115 mm in SVL, the smallest being approximately the body size at hatching (Brodie et al. 1969. Herpetologica 25:223–227). While handling *C. tenuis* on more than a hundred occasions, we have never seen adults or larger juveniles exhibit this posture. The observations occurred on Saltspring Island (26 September 1996, two snakes; 14 March 1997, three snakes), and North Pender Island (24 April 1998, one snake; 7 June 1998, two snakes, including the same individual as seen on 24 April), British Columbia, Canada.

FIG. 1. Two juvenile *Contia tenuis* coiled with the head hidden in a presumed defensive posture.

Coiling into a ball while hiding the head occurs in a wide range of snake species and is especially well documented for boids (Carpenter 1977. *In* Gans and Tinkle [eds.], Biology of the Reptilia, Vol. 7A, Ecology and Behavior, pp. 335–402. Academic Press, New York; Greene 1997. Snakes. The Evolution of Mystery in Nature. Univ. California Press, Berkeley, California. 351 pp.). Looping the body and hiding the head has also been reported for lizards (Bille 1997. Herpetol. Rev. 28:202). The posture apparently functions in protecting the head and other vital parts of the body against predatory attacks. The bulky shape of a coiled snake may also discourage smaller predators from attempting ingestion. We interpret the behavior of juvenile *C. tenuis* as a defense against predators and suggest that an ontogenetic shift in anti-predator behavior occurs during this snake's first year of life.

CROTALUS LEPIDUS MORULUS (Rock Rattlesnake). **REPRODUCTION**. Little is known about the litter size of *Crotalus lepidus morulus*. Data from other subspecies of *C. lepidus* indicate that litter size is between 3–9 (Armstrong and Murphy 1977. The Natural History of Mexican Rattlesnakes. Univ. Kansas Mus. Nat. Hist. Special Publ. 5:1–188; Liner and Chaney 1986. Herpetol. Rev. 17:89). On 25 July 1992, a pregnant female *C. lepidus morulus* (515 mm SVL, 161.8 g) was collected by Fernando Mendoza at Ciénaga del Toro, Nuevo León, México. This snake was maintained in captivity on a diet of mice at the Laboratorio de Herpetología, Universidad Nacional Autónoma de México, Campus Iztacala. On 30 August 1992, the female gave birth to 10 living offspring. The SVL (mean ± SE) of the neonates was 126 ± 12.6 mm (125–146 mm range), and their mass averaged 4.22 ± 0.174 g (3.08–5.30 g). Relative clutch mass was 0.353 (Vitt and Price 1982. Herpetologica 38:237–255).

We thank A. Ramirez-Bautista for comments and suggestions on the manuscript.

Bosque de Chapultepec s/n, C.P. 11850, Distrito Federal, México.

CROTALUS WILLARDI SILUS (Ridge-nosed Rattlesnake). **REPRODUCTION**. There are few accounts of reproduction in *Crotalus willardi silus* (Martin 1975. Bull Maryland Herpetol. Soc. 11:187–189; Armstrong and Murphy 1977. The Natural History of Mexican Rattlesnakes. Univ. Kansas Mus. Nat. Hist. Special Publ. 5:1–188). On 2 May 1993, a gravid female *C. willardi silus* (SVL 500 mm, 144 g) was collected by Mario Mancilla, 2 km south of San Juanito, Chihuahua, México. This snake was maintained in captivity on a diet of mice at the Laboratorio de Herpetología, Universidad Nacional Autónoma de México, Campus Iztacala. On 28 July 1993, the snake delivered two dead embryos and two infertile ova. Later, on 9 August 1993, the snake delivered five live neonates. The SVL (mean ± SE) of the five live young was 169.4 ± 4.28 mm (165–174 mm range), and the average mass was 8.3 ± 0.45 g (7.5–8.5 g). The relative clutch mass was 0.402 (Vitt and Price 1982. Herpetologica 38:237–255). Martin (1975, *op. cit.*) reported the same number of living young for this subspecies.

Although the long period of captivity prior to parturition may have influenced neonate size, our observation is noteworthy because of the paucity of data on reproduction in *C. willardi silus*.

ELAPHE OBSOLETA (Black Rat Snake). **ANTIPREDATOR BEHAVIOR**. On 24 April 1998, an adult *Elaphe obsoleta* was observed defending itself against a red-tailed hawk (*Buteo jamaicensis*). This occurred on a forest access road on the Clemson University Experimental Forest near Central, South Carolina, USA. An adult *B. jamaicensis* was observed standing on top of the *E. obsoleta*. The pronounced size difference between the hawk and the snake, the talon wounds on the snake, the mantling behavior exhibited by the hawk, and the fact that the snake was shedding (as indicated by its blue-opaque eyes), all suggest that initially the hawk was trying to prey upon the snake, and not vice versa. However, the snake had wrapped the lower half of its body around the neck and chest of the hawk, and the hawk had its beak open and tongue protruding. As the struggle continued, the hawk appeared to lose strength and slowly sank to the ground. Even after the hawk appeared dead, the snake retained its hold for at least 10 minutes. The snake was aware of the observer during the struggle as it struck several times. Neither animal was collected so it is unknown if the hawk was diseased.

LAMPROPELTIS TRIANGULUM BLANCHARDI (Blanchard's Milk Snake). **DIET**. Lee (1996. The Amphibians and Reptiles of the Yucatan Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.) suggests that *Lampropeltis triangulum blanchardi* from the Yucatan Peninsula feed primarily on mammals. Here we report a lizard in the diet of *L. t. blanchardi* from the Yucatan Peninsula.

During 1973, C. Radcliffe collected a female *L. t. blanchardi* (43.0 cm SVL, 24.4 g) from the state of Yucatan, México (University of Colorado Museum 60036). This snake contained one intact *Cnemidophorus angusticeps* (8.5 cm SVL, 6.6 g) that had been swallowed headfirst (catalogued under the same UCM number as the snake). These measurements were made on the preserved specimens, after each had been blotted dry with paper towels. This prey item, along with the small size of the snake, suggests that *L. t. blanchardi* on the Yucatan Peninsula may undergo an ontogenetic shift in diet from lizards to mammals, as has been observed for several other species of snakes (e.g., Mackessy 1988. Copeia 1988:92–101).

MICRURUS BROWNI BROWNI (Brown's Coral Snake). **DIET**. A *Micrurus browni browni*, collected on 16 September 1972 from Ocozocautla, México and deposited in the California Academy of Sciences Herpetology Collection (CAS 163739), was discovered by JBS to contain a *Tantilla rubra* (identified by J. A. Campbell) in its stomach. The *M. b. browni* (545 mm SVL, 32.15 g preserved mass) swallowed the *T. rubra* (224 mm SVL, 4.45 g preserved mass) head first. Coral snakes are common predators on snakes, especially small, leaf-litter or fossorial snakes (Greene 1984. Spec. Publ. Univ. Kansas Mus. Nat. Hist. 10:147–162; Seib 1985. Feeding Ecology and Organization of Neotropical Snake Faunas. Ph.D. Dissertation. University of California, Berkeley. 229 pp.). *Micrurus browni* is known to eat *Adelphicos quadrivirgatus*, *Leptotyphlops goudoti bakewelli*, *Tantilla* spp., and *Typhlops braminus* (Blaney and Blaney 1978. Herpetol. Rev. 9:92; Casas-Andreu and Lopez-Forment 1978. An. Inst. Biol. Univ. Nal. Auton. México 49, Ser. Zoología 1:291–294; Greene 1973. The Feeding Habits and Feeding Behavior of New World Coral Snakes. M.A. Thesis. University of Texas at Arlington, 66 pp.). This appears to be the first record of *Micrurus browni browni* eating *Tantilla rubra*.

NERODIA SIPEDON INSULARUM (Lake Erie Water Snake). **DIET**. The round goby (Gobiidae: *Neogobius melanostomus*), a fish native to the Black and Caspian Seas, has become established in the North American Great Lakes in this decade, presumably through release of ballast water by foreign tankers (Jude et al. 1992. Can. J. Fish. Aquatic Sci. 49:416-421). Here we document the inclusion of round gobies in the diet of water snakes (*Nerodia sipedon insularum*) inhabiting the island region of western Lake Erie. As part of an investigation of the distribution and abundance of this snake on the Ohio islands in 1996–1998, 46 prey items were recovered by spontaneous regurgitation or palpation from 41 individual snakes (Table 1). Round gobies constituted 24% of prey recovered from water snakes in 1996–1998. In contrast, gobies were absent among 45 prey items recovered from island snakes in 1989–1992 (King 1993. J. Herpetol. 27:90–94). Spottail shiners (*Notropus hudsonius*) and yellow perch (*Perca flavescens*) were also absent from previous Lake Erie water diet samples, but other Percidae were consumed (King, *op. cit.*; Hamilton 1951. Can. Field Natur. 65:64–65). Mudpuppies (*Necturus maculosus*) were present in previous Lake Erie water snake diet samples but constituted a larger proportion of water snake prey in 1996–1998 than in 1989-1992 (33% vs. 13%, Fisher exact test: $P = 0.045$).

Round gobies are bottom dwellers (Jude et al., *op. cit.*), and so their inclusion along with other benthic vertebrates in the diet of the Lake Erie water snake is not surprising. Whether round gobies will have a net positive or negative effect on water snake populations remains uncertain. Gobies currently occur in high densities in the island region of western Lake Erie (5–7 gobies per m^2 have been observed near some islands; K. Baker, pers. comm.) and thus may represent an abundant food source for water snakes. However, round gobies feed on zebra mussels (Ghedotti et al. 1995. J. Great Lakes Res. 21:665–669), and as a consequence of filter feeding by zebra mussels, may accumulate environmental toxins that could harm water snakes. In addition, round gobies may reduce the densities of other water snake prey (e.g., log perch, *Percina caprodes*, Jude et al. 1995. *In* Munawar et al. (eds.), The Lake Huron Ecosystem: Ecology, Fisheries and Management, pp 447–460. SPB Academic Publishing, Amsterdam).

TABLE 1. Prey species (common name), number of individual prey (number of snakes containing that prey, if different), mean ± SD prey mass (range), mean ± SD snake mass (range), and mean ± SD ratio of prey mass to snake mass (range) for 46 prey items recovered from 41 Lake Erie water snakes.

Prey Species	N	Prey Mass (g)	Snake Mass (g)	Prey:Snake Mass
Neogobius melanostomus (Round Goby)	11 (10)	13.5 ± 8.95 (3.7–30.7)	391.6 ± 158.08 (154.5–568.6)	0.04 ± 0.018 (0.01–0.06)
Notropus hudsonius (Spottail Shiner)	7	4.9 ± 1.51 (2.8–7.3)	424.15 ± 231.90 (76.2–540.0)	0.03 ± 0.043 (0.01–0.10)
Notorus flavus (Stonecat Madtom)	4	73.3 ± 39.91 (32.0–126.0)	570.9 ± 137.49 (418.1–684.6)	0.16 ± 0.053 (0.09–0.19)
Etheostoma blenniodes (Greenside Darter)	3	0.5 ± 0.12 (0.4–0.6)	11.5 ± 4.95 (8.0–15.0)	0.05 ± 0.071 (0.04–0.05)
Perca flavescens (Yellow Perch)*	2	40.9	330.7 ± 382.97 (59.9–601.5)	0.07
Percina caprodes (Log Perch)	4	1.2 ± 0.32 (1.0–1.6)	19.3 ±7.71 (10.0–28.2)	0.09 ± 0.061 (0.05–0.16)
Necturus maculosus (Mudpuppy)	15	53.0 ± 38.08 (14.2–139.5)	528.6 ± 153.63 (237.5–788.0)	0.11 ± 0.060 (0.03–0.24)

* Only one yellow perch was measurable

Prey items recovered in this study will be deposited at the Field Museum of Natural History, Chicago, Illinois. Financial support was provided by the Ohio Division of Wildlife.

KERFIN**, Department of Biological Sciences, Northern Illinois University, DeKalb, Illinois 60115, USA (e-mail: rbking@niu.edu), and **JOHN HAGEMAN**, F. T. Stone Laboratory, Ohio State University, Put-in-Bay, Ohio 43456, USA.

PHILODRYAS PATAGONIENSIS (NCN). **PREDATION.** *Philodryas patagoniensis* feeds on a wide range of prey including frogs, lizards, snakes, fishes, birds, and mammals (Leitão de Araújo and Ely 1980, Iheringia, Sér. Zool., Porto Alegre 55:87–106; Sazima and Haddad 1992, *In* L. C. P. Morellato [ed.], História Natural da Serra do Japi, pp. 212–236. Editora da Unicamp/Fapesp, Campinas; Vanzolini 1948. Rev. Brasil. Biol. 8:308–311). Here we report bird nestlings taken as food in the wild by *P. patagoniensis* in southeastern Brazil.

An individual of this species, ca. 800 mm total length, was found by SPCS in a nest of *Troglodytes aedon* (house wren, Passeriformes, Troglodytidae) that contained three young on 1 April 1984 around 1300 h near Teresópolis, Rio de Janeiro State, Brazil (22°26'S, 42°59'W; 950 m elevation). The nestlings were ca. seven days old. The nest was inside a cavity located at the top of an eroded fence post ca. 5 m from a house. Occasionally, the activity of birds at this nest had been watched in previous days. When the snake was noted, the anterior portion of its body was inside the nest cavity holding one of the young in its mouth; the other two young birds had disappeared from the nest and might have already been swallowed by the snake, which showed a lump in its body. This record supports the idea that *P. patagoniensis* is an opportunistic predator.

We thank Luiz Antonio Pedreira Gonzaga for suggestions, comments on this note, and providing additional information.

Submitted by **SERGIO POTSCH DE CARVALHO E SILVA** and **JOSÉ DUARTE DE BARROS FILHO**, Laboratório de Anfíbios e Répteis, Departamento de Zoologia, Universidade Federal do Rio de Janeiro, Caixa Postal 68044, CEP 21944-970, Rio de Janeiro, RJ, Brazil (e-mail [SPCS]: spotsch@acd.ufrj.br).

THAMNOPHIS SIRTALIS CONCINNUS (Red-spotted Garter Snake). **DIET.** The common garter snake, *Thamnophis sirtalis*, is one of the few known predators of the newt *Taricha granulosa*. Only *T. sirtalis* that occur sympatrically with *T. granulosa* are able to resist the neurotoxin (tetrodotoxin) produced by these newts, and this resistance is variable within and between sympatric populations (Brodie and Brodie 1991, Evolution 45:221–224). Documented resistant populations of garter snakes occur in Benton Co., Oregon; western Lane Co., Oregon; Vancouver Island, British Columbia (Brodie and Brodie 1990, Evolution 44:651–659; Brodie and Brodie 1991, *op. cit.*); and the San Francisco Peninsula (Fox 1952, Herpetologica 8:4–8). We report two separate cases of *Thamnophis sirtalis concinnus* consuming rough-skinned newts, *T. granulosa*, in eastern Lane County, Oregon (USA). To the best of our knowledge, we also provide the first published account of *T. sirtalis* consuming *Plethodon dunni*.

On 25 June 1996 we found a *T. sirtalis concinnus* (449 mm SVL, 26.1 g) dead on USFS road 1506 in the Lookout Creek watershed (T15S R5E sec. 31). Upon dissection, we found two prey items in the stomach of the snake. The most posterior was a partially di-

gested *T. granulosa* (newly metamorphosed) swallowed head first. Anterior to the newt was a Dunn's salamander, *P. dunni* (69 mm SVL, 3.1 g) that was swallowed tail first. Several cerci from nymphal stoneflies (*Calineuria* sp.) were in the small intestine of the snake. These insects likely represent secondary prey items (Fitch 1965, Univ. of Kansas Publ. Mus. Nat. Hist. 15:493–564). Even though the snake was dead when collected, we believe it was not adversely affected by tetrodotoxin because the newt was partially digested when found and because the snake ate the Dunn's salamander after eating the newt.

On 28 July 1997 we found another *T. sirtalis concinnus* (427 mm SVL, 36.0 g) dead on USFS road 15 in the Blue River watershed (T15S R5E sec. 31), 2.4 km NW of the location of the first snake. This animal had swallowed a *T. granulosa* (53 mm SVL, 5.5 g) tail first. No other prey items were found. Intrapopulation resistance to tetrodotoxin in *T. sirtalis* is variable such that certain individuals are immobilized after consuming a newt. Because this specimen was found DOR shortly after consuming a newt, we can not rule out that the newt was the proximal cause of the snake's death.

Individual *T. sirtalis* can move as much as 17 km in a season (Gregory and Stewart 1975, Can. J. Zool. 53:238–245). Because these snakes were found only 2.4 km apart and in connecting watersheds, it is probable that they are from the same population. This population of snakes occurs sympatrically with *T. granulosa* and appears to include individuals that are resistant to tetrodotoxin.

All specimens were deposited in the Texas Natural History Collections of the Texas Memorial Museum, Austin, Texas (1996 *T. sirtalis* and prey = TNHC 59342; 1997 *T. sirtalis* and prey = TNHC 59341) .

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 30, Number 1 (March 1999).

CAUDATA

AMBYSTOMA MACRODACTYLUM (Long-toed Salamander). USA: ALASKA: ALEXANDER ARCHIPELAGO: Vank Island Group, Sokolof Island, NW 1/4 of Sec.15, T62S, R82E, vernal pond off abandoned logging road just upslope of tidal influence on S side of small cove on W side of island. 5 May 1992. Aquatic Collection of the University of Alaska, Fairbanks (UAF 1993-10:28a; also UAF 1993-10:28b [11 larvae]). Verified by Jeff Stoneman. UAF 1993-10:28a is a recently transformed sub-adult specimen taken from under a moss-covered piece of downed-woody debris partially buried in leaf and forest litter about 5 m upslope of the vernal pool in which UAF 1993-10:28b were taken as eggs attached to alder twigs. These specimens represent the first records for the Alexander Archipelago, the first insular records for the species in Alaska, the westernmost state records for the species, and the first records for Sokolof Island and outside the Stikine River drainage. The nearest known mainland records occur in the Stikine River drainage which enters the Pacific Ocean ca. 11 km to the NE (Hodge 1973, HISS News J. 1:23; Hodge 1976, Amphibians and Reptiles in Alaska, the Yukon and Northwest Territories. Alaska Northwest Publ. Co., Anchorage).

Submitted by **BRADFORD R. NORMAN**, 69 Midway Court, Arcata, California 95521, USA.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: TENNESSEE: HARDIN CO: Shiloh National Military Park, located on road adjacent to a temporary pond near Indian Mounds. 7 March 1998. APSU Color Slide 5584. Verified by A. Floyd Scott. Time of collection was 8:00 pm. Conditions at time of collection were 10°C and raining. Extends the presence of disjunct populations from the Coastal Plain in western Tennessee eastward (Redmond and Scott 1996, Atlas of Tennessee Amphibians. Center for Field Biol. Austin Peay St. Univ. Misc. Pub. 12:1–94).

ENSATINA ESCHSCHOLTZII (Ensatina). CANADA: BRITISH COLUMBIA: Kitlope, 53°13'N, 127°51'W. 6 April 1992. John Kelson. RBCM 1911. Verified by Stan Orchard. Clayoquot River, Vancouver Island, 49°12'49"N, 125°29' 41"W. 7, 15, and 21 October 1998. Robyn Scott, David White, Jamie Johansen, and Chris Addison. RBCM Photograph File. Verified by Theodore M. Davis. Specimen from Kitlope was found under a downed log along a river bank in mature forest, and those from Vancouver Island were found at night on the surface of the forest floor, also in mature forest. Kitlope record extends the known range of the species ca. 110 km northward from South Bendinct Arm on the mainland coast. Within a stretch of close to 400 km north of Redona Bay, the salamander is now known from only two localities. To our knowledge, the record from Clayoquot River is the first documentation of the species from the west coast of Vancouver Island. We have an additional record of *E. eschscholtzii* (collected and released on 27 September 1996 after examination by Elke Wind) from 11 km W of Port McNeill on Vancouver Island (50°30'30"N, 127°16'20"W), ca. 160 km northward of the nearest previous locality in Miracle Beach Provincial Park. The paucity of locality records likely reflects a lack of search effort on northern and western Vancouver Island and in the remote, largely roadless mainland coast rather than the absence of the species from the intervening areas.

GYRINOPHILUS PORPHYRITICUS PORPHYRITICUS (Northern Spring Salamander). USA: TENNESSEE: HARDIN CO: Shiloh National Military Park, ca. 100 m from Owl Creek Beaver Pond. 7 March 1998. APSU Color Slide 5583. Verified by A. Floyd Scott. Larval individuals were found in an inground, spring fed cattle trough at 1330 h. Conditions were 12°C and drizzling. Extends range from northern Mississippi to southwestern Tennessee (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts, pp. 285–286). Provides first evidence of this species west of the Central Basin in Tennessee (Redmond

and Scott 1996, Atlas of Tennessee Amphibians. Center for Field Biol. Austin Peay St. Univ. Misc. Publ. 12:1–94).

Submitted by **CRAIG D. WILMHOFF, LIN WILLIAMS, RONALD MACDONALD, SHARON FISHER**, and **JOLENE SLOTHOUBER**, Department of Biology, University of Memphis, Memphis, Tennessee 38152, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: TEXAS: Upshur Co: 4.8 km S Big Sandy. 11 March 1967. Edward Jacquet. SMBU 9317–22. Verified by Stephen L. Williams. First record for county (Dixon 1987, Amphibians and reptiles of Texas, Texas A & M Univ. Press. 434 pp; Dixon 1997, Texas Herpetol. Soc. Spec. Publ. 3:1–14).

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611-7800, USA; **DAVID LINTZ** and **BRYCE C. BROWN**, Strecker Museum, Baylor University, Waco, Texas 76798-7154, USA; **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA.

PLETHODON SERRATUS (Southern Redback Salamander). USA: GEORGIA: Clayton Co: Hampton, Clayton County Water Authority Wetlands Center, 2755 Freeman Road. Swamp located 100 m SW jct. of Pate's Creek and Freeman Road. Two individuals found on hill between the location where Turkey Creek and Pate's Creek enter the wetland. 14 February 1998. Stacy Smith. SOCM 813. Verified by John Jensen. New county record (Williamson and Moulis 1994, Distribution of Amphibians and Reptiles in Georgia. Savannah Sci. Mus. Spec. Pub. 3:1–712).

Submitted by **STACY N. SMITH**, Clayton County Water Authority Wetlands Center, 2755 Freeman Road, Hampton, Georgia 30228, USA.

PSEUDOTRITON RUBER VIOSCAI (Southern Red Salamander). USA: TENNESSEE: Hardin Co: Shiloh National Military Park, 10m from headwaters underneath bark of log. 7 March 1998. APSU Color Slide 5582. Verified by A. Floyd Scott. Individual was found at 10 am. Conditions were 12°C and drizzling. Provides further evidence of the disjunct populations of this species in the eastern two-thirds of the Coastal Plain in western Tennessee (Redmond and Scott 1996, Atlas of Tennessee Amphibians. Center for Field Biol. Austin Peay St. Univ. Misc. Publ. 12:1–94).

Submitted by **CRAIG D. WILMHOFF, LIN WILLIAMS, RONALD MACDONALD, SHARON FISHER**, and **JOLENE SLOTHOUBER**, Department of Biology, University of Memphis, Memphis, Tennessee 38152, USA.

ANURA

EUPSOPHUS VERTEBRALIS. ARGENTINA: RÍO NEGRO: Bariloche Department Nahuel Huapi National Park, Puerto Blest, 41°02'S, 71°49'W. March 1973. A. Barrio. CENAI 7281 (presently deposited at Museo Argentino de Ciencias Naturales "Bernardino Rivadavia", Buenos Aires). Verified by J. R. Formas. First record for Argentina. Adult male (SVL 49.5 mm) collected in a temperate humid forest of coihue (*Nothofagus dombeyi*) with some elements of Chilean Valdivian forest, e.g., mañiú hembra (*Saxegothaea conspicua*), palo santo (*Dasyphyllum diacanthoides*), and huahuán (*Laureliopsis philippiana*). This frog is found in the richest region of amphibian species inhabiting the Patagonian temperate forests east of the Andes, sharing the area with *Eupsophus calcaratus, Batrachyla antantardica, B. leptopus, B. taeniata, Hylorina sylvatica, Alsodes australis, A. monticola, Pleurodema thaul, Bufo variegatus*, and *Rhinoderma darwinii*. The species is distributed in Chile from Ramadillas, 37°18'S, 73°17'W to Bahía Mansa, 40°30'S, 73°40'W (Formas 1989, Proc. Biol. Soc. Washington 102:568–576). Extends the distribution of the species to E of the Andes mountains, 168 km SE from the southernmost, previously known locality.

Submitted by **NÉSTOR G. BASSO**, Sección Herpetología, Departamento Científico Zoología Vertebrados, Museo de La Plata, Paseo del Bosque s/n, 1900 La Plata, Argentina, and **CARMEN A. ÚBEDA**, Centro Regional Bariloche, Universidad Nacional del Comahue, Unidad Postal Universidad, 8400 Bariloche, Argentina.

HYLA BIOBEBA. BRAZIL: GOIÁS: Municipality of Silvânia: Estaçao Florestal de Experimentação (ca. 16°39'26"S, 48°36'16"W; 900 m elev.). 2 June 1995. R. P. Bastos, J. A. O. Motta, and D. Blamires. Verified by J. P. Pombal, Jr. Museu Nacional – Universidade Federal do Rio de Janeiro (MNRJ) 17422–23. First documented state record.

Submitted by **ROGÉRIO P. BASTOS** and **DANIEL BLAMIRES**, Departamento de Biologia Geral, UFG, C.P. 131, 74001-970, Goiâna, Goiás, Brazil, **REUBER A. BRANDÃO** and **ANTÔNIO SEBBEN**, Laboratório de Fisiologia Animal, UnB, 70910-900, Brasília, DF, Brazil.

HYLA CINEREA (Green Treefrog). USA: TENNESSEE: Stewart Co: Land Between The Lakes (LBL), Bear Creek Waterfowl Management Area, W shore of Barkley Lake at River Mile 85 in slough adjacent to Cow Creek (36°31'30"N, 87°52'47"W). Four adult males in submerged black willow trees (*Salix nigra*). 14–15 June 1998. Brant Smith and Christina Therrell. Austin Peay State University Museum of Zoology (APSUMZ 5744–45); Barkley Wildlife Management Area, E side of Barkley Lake at River Mile 88 N of Dover (36°29'40"N, 87°50'30"W). Adult male in black willow tree in flooded field. 28 June 1998. Brant Smith. APSUMZ 5743; Cross Creeks National Wildlife Refuge (CCNWR), W side of Barkley Lake at River Mile 91 just N of CCNWR headquarters (36°30'00"N, 87°47'15"W). Three adult males in black willows in adjacent river sloughs (many more calling from surrounding vegetation). 28 July 1998. Brant Smith and Christina Therrell. APSUMZ 5954. All specimens verified by A. Floyd Scott. First records from Cumberland River drainage in Tennessee (Snyder 1972, Amphibians and Reptiles of Land Between The Lakes, Tennessee Valley Authority, Golden Pond, Kentucky. 90 pp.; Redmond and Scott 1996, Atlas of Amphibians in Tennessee, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94).

Submitted by **BRANT T. SMITH** and **CHRISTINA L. THERRELL**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

ODONTOPHRYNUS CULTRIPES. BRAZIL: GOIÁS: Municipality of Silvânia: Estaçao Florestal de Experimentação (ca. 16°39'26"S, 48°36'16"W; 900 m elev.). 9 October 1995. R. P. Bastos, J. A. O. Motta, and D. Blamires. Verified by J. P. Pombal, Jr. Museu Nacional – Universidade Federal do Rio de Janeiro (MNRJ) 17426. Adult male (SVL 61.1 mm) captured during vocalization. First state record.

Submitted by **ROGÉRIO P. BASTOS**, Departamento de Biologia Geral, UFG, C.P. 131, 74001-970, Goiâna, Goiás, Brazil, **JOSÉ AUGUSTO O. MOTTA**, IBAMA, Rua 229, n. 95, Sl. Universitário, 74605-080, Goiâna, Goiás, Brazil, **REUBER A. BRANDÃO** and **ANTÔNIO SEBBEN**, Laboratório de Fisiologia Animal, UnB, 70910-900, Brasília, DF, Brazil.

OSTEOCEPHALUS LANGSDORFFII. BRAZIL: SÃO PAULO: ITIRAPINA: 22°13'52"S, 47°51'11"W, 770 m elev. 15 October 1998. M. T. Almeida and R. Nunes. Collection Célio F. B. Haddad, deposited in Departamento de Zoologia da Universidade Estadual Paulista, Rio Claro, SP; Brazil. (CFB 2980, adult male). Verified by C. F. B. Haddad. Extends known range ca. 76 km NW from Poá Municipality, São Paulo (Cochran 1955, Bull. U.S. Natl. Mus. 206:73–75).

Submitted by **MARÍLIA T. DE ALMEIDA** (e-mail: matal@rc.unesp.br) and **RENATO NUNES** (e-mail: renatonunes@uol.com.br), Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, C.P. 199, 13506—900, Rio Claro—São Paulo, Brazil.

OTOPHRYNE PYBURNI. VENEZUELA: ESTADO AMAZONAS: Parima B, Sierra Parima, 1100 m elevation. 7 August 1986. J. Chiappino. Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (EBRG 1868). Upper Cuao River. 30 August 1987. S. Zent. EBRG 1872. Apepada, Upper Ventuari River, 28 June 1980. M. Colchester. EBRG 1905. All verified by Gilson Rivas. This recently described species (Campbell and Clarke 1998, Herpetologica 54:301–317) has been reported formerly as *Otophryne robusta* in southern Venezuela by McDiarmid and Paolillo (1988, *In* Brewer-Carmas (ed.), Cerro de la Neblina, Resultados de la Expedición 1983–1987. FUDECI, Caracas) and by Rivero (1967, Carib. J. Sci. 7:145–154). EBRG 1872 represents the northernmost known locality for the species, 500 km NW of the previous northernmost report, Ugueto, upper Orinoco (Rivero 1967, *op. cit.*).

Submitted by **CISAR LUIS BARRIO A.**, Fundación para el Desarrollo de las Ciencias Físicas, Matematicas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

OTOPHRYNE STEYERMARKI. VENEZUELA: ESTADO BOLÍVAR: Río Marajano, Meseta de Jaua. 1800 m elev. 2 March 1974. P. A. Bermúdez. Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (EBRG 0008). Verified by Gilson Rivas. Elevated to specific status by Campbell and Clarke (1998, Herpetologica 54:301–317), previously considered a subspecies of *Otophryne robusta* (Rivero 1967, Carib. J. Sci. 7:155–158). Until now, this species has been considered endemic to the Chimanta massif in southern Venezuelan Guayana (Gorzula 1985, Herpetol. Rev. 16:102–103; Gorzula 1992, *In* O. Huber [ed.], El Macizo del Chimanta. Oscar Todtmann Editores, Caracas, Venezuela). Extends known distribution of species 250 km to the WSW, displaying a wider distribution through the pantepui region.

Submitted by **CISAR LUIS BARRIO A.**, Fundación para el Desarrollo de las Ciencias Físicas, Matematicas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

PSEUDACRIS BRACHYPHONA (Mountain Chorus Frog). USA: TENNESSEE: HARDIN CO: Shiloh National Military Park, temporary pond near Indian Mounds. 7 March 1998. APSU Color Slide 5585. Verified by William H. N. Gutzke. Found calling from a temporary pond at 2000 h. Conditions at time of collection were 10°C and rainy. Extends range westward to the eastern portion of the Coastal Plain of western Tennessee (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts, pp. 329–330). Provides first evidence of the species west of Marion County in Tennessee (Redmond and Scott 1996, Atlas of Tennessee Amphibians. Center for Field Biol. Austin Peay St. Univ. Misc. Publ. 12:1–94).

Submitted by **CRAIG D. WILMHOFF**, **LIN WILLIAMS**, **RONALD MACDONALD**, **SHARON FISHER**, and **JOLENE SLOTHOUBER**, Department of Biology, University of Memphis, Memphis, Tennessee 38152, USA.

RANA PALUSTRIS (Pickerel Frog). USA: TEXAS: SABINE CO: 16.1 km S Hemphill. 26 April 1969. Dennis Spence. SMBU 9063. Verified by Stephen L. Williams. First record for county (Dixon 1987, Amphibians and Reptiles of Texas, Texas A & M Univ. Press. 434 pp.; Dixon 1997, Texas Herpetol. Soc. Spec. Publ. 3:1–14).

Submitted by **DAVID L. AUTH**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611-7800, USA; **DAVID LINTZ** and **BRYCE C. BROWN**, Strecker Museum, Baylor University, Waco, Texas 76798-7154, USA; **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA.

SAURIA

ANOLIS CRISTATELLUS (Puerto Rican Crested Anole). USA: FLORIDA: BREVARD CO: on grounds of Riverside Inn (formerly Howard Johnson's Inn) on U.S. Rt. 1, ca 2.4 km S jct. of Florida Rt. 402 and U.S. Rt. 1 (28°35'61"N, 80°48'08"W). 4 August 1998. Benjamin J. Seigel. LSUMZ 80413. Verified by Brian I. Crother and Frank Burbrink. New county record; extends range ca. 310 km N of localities in Dade County (Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89) and represents the second Florida county in which this introduced species is known to occur (Walter Meshaka, pers. comm.). No other specimens were found in two subsequent visits to this site, but local residents report having seen similar lizards in recent months.

Submitted by **BENJAMIN J. SEIGEL**, **NADIA A. SEIGEL**, and **RICHARD A. SEIGEL**, Department of Biological Sciences, Southeastern Louisiana University, SLU 10736, Hammond, Louisiana 70402, USA (e-mail: rseigel@selu.edu).

CROTAPHYTUS COLLARIS (Eastern Collared Lizard). USA: ARIZONA: PINAL CO: N slope Gold Mine Mountain, Santan Mountains, 33°11'05"N, 111°38'24"W. 3 June 1999. Matthew Flowers and Brian K. Sullivan (BKS 1125; LSUMZ 80951). Verified by Jim McGuire. Adult male in rocky, Arizona Upland Biotic Community, 520 m elev. Extends range 35 km SW of previous locality in the Superstition Mountains, and documents taxon in low elevation Sonoran Desert, within 25 km of *C. nebrius* (Sacaton Mountains).

Submitted by **MATTHEW A. FLOWERS**, Department of Biology, Arizona State University, Tempe, Arizona 85287, USA, and **BRIAN K. SULLIVAN**, Department of Life Sciences, Arizona State University West, Phoenix, Arizona 85069, USA.

CYRTOPODION KOTSCHYI (Kotschy's Gecko). HUNGARY: SOMOGY COUNTY: Siofok municipality, Balatonszeplak-felso. August 1998. G. Koszegi. Verified by Zoltan Korsos. Hungarian Natural History Museum (HNHM photographs F-98/1–6, three individuals). First country record. This species is not a native member of the Hungarian herpetofauna. Specimens of Bulgarian origin were released by an amateur herpetologist in his house in 1985, which resulted in the establishment of a viable and reproducing colony. Current numbers are believed to be less than a few dozen individuals. Another colony was introduced to a house wall in Budapest Municipality, District 11, Budaorsiut, by another hobby-

ist in the early 1980s. This second colony still flourishes, but due to intensified usage and reconstruction works in the area, it is unlikely to grow and expand substantially in the future.

Submitted by **BALAZS FARKAS**, **BEATA UJVARI**, Department of Zoology, Hungarian Natural History Museum, Pf. 137, H-1431 Budapest, Hungary, and **GABOR KOSZEGI**, Nemetvolgyi ut 34, H-1126 Budapest, Hungary.

OPHISAURUS COMPRESSUS (Island Glass Lizard). USA: GEORGIA: GLYNN CO: NE end of Little St. Simons Island. 11 September 1996. John Jensen and Bruce Means. UGAMNH 32465. First island record (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712). Many individuals observed in muhley grass (*Muhlenbergia capillaris*) and wax myrtle (*Myrica cerifera*) dominated interdunal swales.

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@mail.dnr.state.ga.us).

PHYMATURUS PATAGONICA. ARGENTINA: RIO NEGRO: 25 de Mayo Department: S edge of Ruta Provincial Nº 8, 40°17'13"S, 68°27'32"W, 900–1000 m elev., 17 km S San Antonio del Cuy. 11 March 1999. L. J. Avila, M. Morando, and D. R. Perez. Herpetological collection, Fundación Miguel Lillo, Tucumán, Argentina (FML 8394–95). Verified by F. Lobo. Northernmost record in Argentina and first record for Río Negro Province (Cei 1986, Mon. IV Mus. reg. Sci. Nat. Torino. 527 pp.). Nearest record for species is Dolavon (43°18'S, 65°40'W), Gaiman Department, Chubut, ca. 400 km airline SE (Cei and Castro 1973, J. Herpetol. 7:237–247). This species has geographic variation that makes it difficult to identify some populations, and many diagnostic characters for its differentiation from *P. somuncurensis* may be of doubtful value. The individuals of this population show a remarkable chromatic variation, from almost black to olive green, with variations in the dorsal pattern ranging from white dots to transverse black bands. More than 20 specimens were collected basking on isolated rock outcrops or taking refuge in small crevices.

Submitted by **LUCIANO JAVIER AVILA**, **MARIANA MORANDO**, CRILAR-CONICET, Mendoza y Entre Ríos s/n, C.P. 5301, Anillaco (La Rioja), Argentina, and **DANIEL ROBERTO PEREZ**, Instituto Superior de Formación y Perfeccionamiento Docente de Villa Regina, San Luis 327, Villa Regina (Río Negro), Argentina.

SERPENTES

BOIGA MULTOMACULATA (Marble Cat Snake). LAO P.D.R.: LUANG PRABANG PROVINCE: Route 13, 12 road km S Luang Prabang proper. 23 May 1998. B. Buzas, B. Farkas, and Z. Karacsonyi. Verified by Zoltan Korsos. Hungarian Natural History Museum (HNHM photographs D-98/4–6, one individual). Deuve (1970, Serpents du Laos. Mem. ORSTOM 39:1–251) stated that this species occurred in all Laotian provinces, but provided only four actual localities, none of which is in Luang Prabang.

Submitted by **BALAZS FARKAS**, Department of Zoology, Hungarian Natural History Museum, Pf. 137, H-1431 Budapest, Hungary, and **UWE FRITZ**, Staatliches Museum fur Tierkunde, A.-B.-Meyer-Bau, Konigsbrucker Landstrasse 159, D-01109 Dresden, Germany.

CLELIA BICOLOR. ARGENTINA: MISIONES: Departamento Apostoles: on Provincial Route 105 (27°47'S, 55°46'W). 22 January 1999. P. M. Cacivio. Herpetological Collection of Fundación Miguel Lillo, San Miguel de Tucumán, Argentina (FML 8475). Verified by G. Scrocchi. First province record; confirms presumed distribution and extends known range at least 285 km NW from previous sites (Scrocchi and Viñas 1990, Boll. Mus. reg. Sci. nat. Torino 8[2]:490–495; Cei 1993, Monogr. XIV. Mus. reg. Sci. nat. Torino, p. 532; Alvarez et al. 1996, Facena 12:127; Williams and Francini 1991, Mus. reg. Sci. nat. Torino 9[1]:62).

Submited by **PEDRO MATIAS CACIVIO**, Centro de Producción de Sueros Antiofidicos, José Mármol 243, Caixa Postal 3500, Resistencia, Chaco, Argentina (e-mail: cacivio@arnet.com.ar & cacivio@hotmail.com).

CROTALUS HORRIDUS (Timber Rattlesnake). USA: TEXAS: SAN AUGUSTINE CO: roadkill found on FM 353, ca. 4 km S Shelby County line. Rattles had been removed. 22 May 1999. J. Howard Williamson. SFAVM 4894. Verified by Michael B. Keck. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Press, College Station. 434 pp.).

Submitted by **DANIEL SAENZ**, **D. CRAIG RUDOLPH**, and **J. HOWARD WILLIAMSON**, Wildlife Habitat and Silviculture Laboratory, Southern Research Station, USDA Forest Service, Nacogdoches, Texas 75962, USA.

ENHYDRIS PLUMBEA (Yellowbelly Water Snake). LAO P.D.R.: VIENTIANE MUNICIPALITY: Vientiane proper, city "wasteland." 16 May 1998. B. Buzas, B. Farkas, and Z. Karacsonyi. LUANG PRABANG PROVINCE: Luang Prabang proper, city "park." 21 May 1998. Same collectors. Verified by Zoltan Korsos. Hungarian Natural History Museum (HNHM 98.47.1–48.1). Deuve (1970, Serpents du Laos. Mem. ORSTOM 39:1–251) stated that this very common species occurred in all Laotian provinces, but provided no actual localities.

Submitted by **BALAZS FARKAS**, Department of Zoology, Hungarian Natural History Museum, Pf. 137, H-1431 Budapest, Hungary, and **UWE FRITZ**, Staatliches Museum fur Tierkunde, A.-B.-Meyer-Bau, Konigsbrucker Landstrasse 159, D-01109 Dresden, Germany.

LAMPROPELTIS TRIANGULUM ANDESIANA. VENEZUELA: MIRIDA: La Carbonera. 25 August 1961. J. Ojasti. Museo de Biología, Universidad Central de Venezuela, Caracas (MBUCV-1654). Vía La Azulita, 2000 m elev. 1980. J. Pefaur. Colección de Vertebrados Universidad de los Andes (CVULA 3150). La Otra Banda, 2.4 km SSW Bailadores, 1850 m elev. 2 October 1995. Collector unknown. TACHIRA: Betania, distrito Junín, Tama. 17 July 1977. P. M. Delgado. Museo de Ciencias Naturales, Caracas (MCNC 6830, 6843, 6864, 6868). All verified by O. Fuentes. Previous authors (Aleman 1952, Mem. Soc. Cien. Nat. La Salle 13[35]:205–225; Roze 1966, La Taxonomía y Zoogeografía de los Ofidios de Venezuela. Ediciones de la Biblioteca, Universidad Central de Venezuela, Caracas; Lancini 1979, Serpientes de Venezuela. Armitano Ed., Caracas; Lancini and Kornacker 1986, Die Schlangen von Venezuela. Verlag Armitano, Caracas) assigned this population to *Lampropeltis triangulum micropholis*, previously the only subspecies recognized in South America until the description of *L. t. andesiana* by Williams (1978, Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. Publ. Biol. Geol. Milw. Publ. Museum 2:258). Specimens of *Lampropeltis triangulum* from Venezuela are easily distinguished from the western subspecies, *L. t. micropholis*, using Williams (1978, *op. cit.*). Distribution in Venezuela is restricted to the Andes, in the Cordillera de Mirida (Mirida state), Tama (Tachira state), and Sierra de Perija (Zulia state). The single citation out of the Andean range in "El Avila" (Distrito Federal) at the Coastal Range can not be con-

firmed, because the voucher specimen (MHNLS 1434) is apparently lost.

Submitted by **CISAR LUIS BARRIO A.**, Fundación para el Desarrollo de las Ciencias Físicas, Matematicas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve), and **LUIS FERNANDO NAVARRETE**, Colección de Herpetología, Fundación Museo de Ciencias, Caracas, Venezuela (e-mail: mcienci2@reacciun.ve).

PHALOTRIS NASUTUS. BRAZIL: MATO GROSSO DO SUL: Xavantina between the Paraná River and the highlands of the Serra de Maracajú, 21°15'S, 52°48'W. Universidade Federal de Mato Grosso, herpetological collection (UFMT 958). Young male. Verified by M. Di Bernardo. Found in a region that is transitional from Cerrado to Chaco ecophysiographic districts; enlarges substantially distribution to the west, based on the revision by Ferrarezzi (1993, Mem. Inst. Butantan 55[1]:27); author stated that *P. nasutus* was the easternmost species of the *nasutus* group, but this record is far to the west, making this taxon the most widespread member of that group.

Submitted by **THALES DE LEMA**, Departamento de Biologia, Faculdade de Biociências, Pontificia Universidade Catolica de Rio Grande do Sul, P.O. Box 1429, Porto Alegre, RS 90619-900, Brazil (e-mail: crothales@pucrs.br).

PSEUDOXENODON MACROPS (Big-eyed Bamboo Snake). LAO P.D.R.: CHAMPASSAK PROVINCE: Dong Hua Xao National Biodiversity Conservation Area, 2 km S Nong Luang village, bank of Touay-Guai stream, 15°4'N, 106°13'E, 800 m. 5 April 1998. O. Merkl and G. Csorba. Verified by Zoltan Korsos. Hungarian Natural History Museum (HNHM photographs D-98/1–3, one individual). Deuve (1970, Serpents du Laos. Mem. ORSTOM 39:1–251) did not provide any Laotian locality for *Pseudoxenodon angusticeps*, of which he considered *P. macrops* a synonym.

Submitted by **BALAZS FARKAS**, Department of Zoology, Hungarian Natural History Museum, Pf. 137, H-1431 Budapest, Hungary, and **UWE FRITZ**, Staatliches Museum fur Tierkunde, A.-B.-Meyer-Bau, Konigsbrcker Landstrasse 159, D-01109 Dresden, Germany.

UMBRIVAGA PYGMAEA. BRAZIL: AMAZONAS: Tefé (03°22'S, 64°42'W). Collected during an Instituto Butantan expedition from September to November 1952. Instituto Butantan (IB 15104). Verified by R. Fernandes. Species was originally described as *Liophis pygmaeus* by Cope (1868, Proc. Acad. Nat. Sci. Philadelphia 103) based on a Peruvian specimen from Marañon River, near the mouth of Napo River. Peters and Orejas-Miranda (1970, U.S. Natl. Mus. Bull. 297) recorded this taxon from the upper Amazonian region of Colombia and Ecuador. There is no previous record of this species or genus from Brazil. The record reported herein extends the known distribution more than 800 km east of the type locality.

Submitted by **DANIEL S. FERNANDES**, **FRANCISCO L. FRANCO**, and **VALDIR J. GERMANO**, Laboratório de Herpetologia, Instituto Butantan, Avenida Vital, Brazil 1500, CEP 05503-900, São Paulo, São Paulo, Brazil.

XENOCHROPHIS PISCATOR (Checkered Keelback). LAO P.D.R.: VIENTIANE PROVINCE: Vang Vieng, bank of Nam Song River. 18 May 1998. B. Buzas, B. Farkas, and Z. Karacsonyi. Hungarian Natural History Museum (HNHM 98.49.1). Verified by Zoltan Korsos. Deuve (1970, Serpents du Laos. Mem. ORSTOM 39:1–251) stated that this very common species occurred throughout the tributary of the Mekong River, but provided no actual localities.

New Parish Records of Amphibians and Reptiles from Louisiana

JOHN G. HIMES
Museum of Life Science, Louisiana State University in Shreveport
One University Place, Shreveport, Louisiana 71115-2399, USA

Present address: Department of Biological Sciences, Box 5018
University of Southern Mississippi, Hattiesburg, Mississippi 39406-5018, USA

Louisiana harbors 49 species of amphibians and 96 species of reptiles (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge. 300 pp.). Dundee and Rossman (1989, *op. cit.*) mapped the known distributions of amphibian and reptile species in Louisiana. However, published records for most amphibian and reptile species in Louisiana are lacking from many parishes, particularly in the north. The following is a list of specimens representing new locality records and filling in some of the current distribution gaps. All specimens are deposited in the Louisiana State University in Shreveport Museum of Life Sciences (LSUS). All species identifications were verified by Laurence M. Hardy.

Ambystoma talpoideum (Mole Salamander). USA: LOUISIANA: Bienville Parish: 0.2 mi. N and 0.2 mi. W jct. T16N, R7W. L. M. Hardy and J. G. Himes. 11 August 1996. LSUS 6993.

Plethodon serratus (Southern Redback Salamander). De Soto Parish: SE Mansfield. A. B. McPherson. April 1995. LSUS 6378. Extends distribution northwestward from nearest known locality in Natchitoches Parish (Keiser and Conzelmann 1969, J. Herpetol. 3:189–191).

Acris gryllus gryllus (Southern Cricket Frog). St. Charles Parish: Bonnet Carre Spillway, E Border, 7 mi. off Airline Highway. M. Haik. 9 April 1979. LSUS 6676.

Hyla avivoca (Bird-voiced Treefrog). Bossier Parish: Bodcau Wildlife Area near Whittington Road. D. Wyrick. April 1991. LSUS 68050. Webster Parish: 5.6 mi. W and 1.0 mi. S Leton. L. M. Hardy and L. R. Raymond. 2 June 1998. LSUS 6986–90. First records from the northwestern quarter of the state (Dundee and Rossman 1989, *op. cit.*).

Chrysemys picta dorsalis (Southern Painted Turtle). De Soto Parish: 0.2 mi. W and 0.5 mi. S Wallace Lake Dam Spillway. 1992. LSUS Herpetology Class. 26 February 1992. LSUS 5429. Skeleton only.

Graptemys pseudogeographica kohnii (Mississippi Map Turtle). Webster Parish: 5 mi. S Sibley. L. Sanders. 27 April 1984. LSUS 5361.

Sternotherus odoratus (Common Musk Turtle). Bossier Parish: no specific locality data. T. Cottrell. 25 February 1984. LSUS 1999.

W bank Red River, 1.2 mi. E and 1.6 mi. N LSUS campus. L. M. Hardy. 2 October 1980. LSUS 5418. De Soto Parish: Wallace Lake at spillway. Collector unknown. 9 August 1972. LSUS 3424. S end Wallace Lake Dam. L. M. Hardy. 1 October 1972. LSUS 4297. 0.2 mi. W and 0.5 mi. S Wallace Lake Dam Spillway. 1992. LSUS Herpetology Class. 26 February 1992. LSUS 5426–27. Skeleton only.

Terrapene carolina triunguis (Three-toed Box Turtle). Claiborne Parish: 2.4 mi. W and 1.7 mi. N Summerfield on paved road. L. M. Hardy. 31 July 1970. LSUS 5709. Skeleton only.

Anolis carolinensis (Green Anole). Webster Parish: 32°25'77"N, 93°25'10"W. C. B. Erickson. 2–3 March 1974. LSUS 6979–81.

Eumeces anthracinus pluvialis (Southern Coal Skink). West Feliciana Parish: Tunica Hills SPG–1965. Collector and date unknown. LSUS 6813. Extends distribution westward from nearest known localities in East Feliciana Parish (Dundee and Rossman 1989, *op. cit.*).

Ophisaurus attenuatus attenuatus (Western Slender Glass Lizard). De Soto Parish: 1.5 mi. N and 3.8 mi. E (via Linwood Avenue) Stonewall. L. M. Hardy. 5 August 1970. LSUS 1138. 5.8 mi. E from jct. of Stonewall-Frierson Road and Linwood Avenue. S. Micinski. 14 June 1976. LSUS 3985.

Crotalus horridus (Timber Rattlesnake). Claiborne Parish: 4 mi.S Haynesville on Rt. 79. D. Bounds. 13 October 1975. LSUS 3436. De Soto Parish: 3.7 mi. E and 3.5 mi. S jct. De Soto, Caddo, Red River Parishes. C. Warren. 26 August 1986. LSUS 5215. 0.5 mi. S Rt. 346. J. R. Harris. 29 September 1987. LSUS 5338.

Lampropeltis getula holbrooki (Speckled Kingsnake). Claiborne Parish: 3.6 mi. N and 4.3 mi. W Scottsville. L. M. Hardy. 30 July 1970. LSUS 1451.

Micrurus fulvius tener (Texas Coral Snake). De Soto Parish: Logansport. Collector unknown. 23 August 1991. LSUS 5729. Red River Parish: 3 mi. S (via U.S. Rts. 71 and 84), 1 mi. into woods from highway, T12N, R8W. C. Diramus. 9 May 1972. LSUS 1790. 2 mi. W Coushatta. M. Sloan. 1 June 1972. LSUS 1994. Coushatta, Alex Penny Farm. S. Penny. 23 November 1973. LSUS 2471. Coushatta. G. Wise. 23 November 1973. LSUS 2724. Coushatta, Alex Penny Farm. L. A. Dye. 23 November 1973. LSUS 2728.

Nerodia rhombifer rhombifer (Diamondback Water Snake). Lafourche Parish: Rt. 1, 3 mi. outside of Thibodeaux. B. Wilson. 16 April 1993. LSUS 6886.

Regina grahamii (Graham's Crayfish Snake). Bienville Parish: Loggy Bayou. Cox and Divers. 3 April 1993. LSUS 6274.

Regina rigida sinicola (Gulf Crayfish Snake). Bienville Parish: 2.1 km E Kepler Creek Lake Bridge. 14 September 1996. J. G. Himes. LSUS 6991.

Storeria occipitomaculata obscura (Florida Redbelly Snake). De Soto Parish: 2 mi. N (via Louisiana Rt. 175) Frierson. L. M. Hardy. 23 June 1970. LSUS 930. on Linwood Avenue, 6 mi. S Flournay-Lucas Road. B. Legrande. 29 July 1970. LSUS 3437. 0.4 mi. E jct. of Stonewall-Frierson Road and Linwood Avenue. S. Micinski. 14 June 1976. LSUS 3995. 5.3 mi. N and 1.3 mi. E Mansfield (jct. U.S. Rt. 84 and Louisiana Rt. 175). S. Micinski. 8 September 1976. LSUS 4031. 3.8 mi. E and 0.4 mi. N Stonewall. L. M. Hardy. 15 June 1992. LSUS 5798. Red River Parish: 1.9 mi. E and 4.4 mi. S Hall Summit. L. M. Hardy. 9 September 1974. LSUS 3473.

Thamnophis sauritus sauritus (Eastern Ribbon Snake). East Baton Rouge Parish: 14157 E Covett Road, Baton Rouge. T. Papaneri. 15 April 1989. LSUS 6396. Extends distribution southward from nearest known locality in East Feliciana Parish and represents furthest southwestern locality recorded for this species (Dundee and Rossman 1989).

Virginia striatula (Rough Earth Snake). Claiborne Parish: Corney Lake campground. A. B. McPherson. April 1989. LSUS 6290.

Virginia valeriae elegans (Western Earth Snake). Claiborne Parish: 1 mi. NW (via Louisiana Rt. 2) Summerfield. L. M. Hardy. 31 July 1970. LSUS 270. 1.5 mi. NW Haynesville. D. Bounds. 23 February 1975. LSUS 3515. De Soto Parish: 2 mi. N (by road) jct. Linwood and Frierson Roads. L. M. Hardy. 29 June 1970. LSUS 268. 0.25–0.5 mi. N (by Colquitt Road) jct. Colquitt Road and Williams Road. L. M. Hardy. 30 June 1970. LSUS 269. 3 mi. N (on Linwood Avenue) jct. with Frierson Road. L. M. Hardy. 18 September 1970. LSUS 272.

New Anuran Records from the Floresta Nacional de Caxiuanã, Eastern Amazon, Brazil

** corresponding author*

The first list of the herpetofauna of Caxiuanã was published by Avila-Pires and Hoogmoed (1997) and represents one of the few anuran lists available for the eastern Amazon Basin (other than Crump 1971). Considering that most anuran species in Amazonia have sparse distribution records or those only vaguely described in the literature, for example "Brazilian Amazon Basin," the records for Caxiuanã, whether or not they extend the range of a particular taxon, may help to fill the ranges for many little-recorded species. The Floresta Nacional de Caxiuanã (FNC) is a major Conservation Unit (333,000 ha) located between the basins of the Xingu and Tocantins Rivers, in the southern drainage of the Rio Amazonas (01°42'33"S, 51°31'45"W), in the eastern Brazilian Amazon, 340 km from Belém, in the state of Pará, Brazil. Annual rainfall in the region is between 2000 and 2500 mm, mean temperature around 26°C, and relative humidity not less than 85% (Lisboa 1997). A distinct dry season occurs between late June and middle November. About 85% of the FNC is covered by primary forest not subjected to seasonal flooding ("terra-firme"); other habitats include savannas, secondary vegetation and seasonally flooded areas of "várzeas" and "igapós" (Almeida et al. 1993; Lisboa et al. 1997).

Below we present the results of the most recent field work, conducted mainly by the senior author during eight field trips (each of about twenty days) between February 1996 and April 1998, which added eleven anuran species to the 29 described in Avila-Pires and Hoogmoed (*op. cit.*). Verifications of the specimens and respective

identifications were supplied by Marinus S. Hoogmoed, except for *Bufo castaneoticus*, which was identified earlier by Janalee P. Caldwell (March 1996) and M. S. Hoogmoed (April 1997). All the specimens are housed in the herpetological collection of the Department of Zoology, Museu Paraense Emílio Goeldi (MPEG).

Hylidae

Hyla lanciformis. Laranjal Stream, in aquatic vegetation. 7 February 1998. MPEG 8829. Laranjal Stream, in aquatic vegetation. 4 April 1998. MPEG 8830. Distribution of the species has been described as "middle and upper Amazon basin and Venezuela" (Frost 1985), with published records in the Juruá, Urucu, Purus and Madeira River basins (Heyer 1977; Gascon and Pereira 1993). This is the first record for the state of Pará and the eastern Amazon basin.

Hyla leucophyllata. Laranjal Stream, in aquatic vegetation. 7 February 1998. MPEG 8801–08. The species has a broad distribution in the Amazon basin and was recorded in the Belém region by Crump (1971).

Hyla melanargyrea. Bank of the Curuá River, inside a house. May 1997. MPEG 8811–12. This is not a characteristic Amazonian species. It occurs mostly in central and northeastern Brazil and Suriname (Frost 1985; Duellman 1993), and has been recorded for the Belém region (Crump 1971).

Hyla punctata. Laranjal Stream, in aquatic vegetation. 4 April 1998. MPEG 8813. First record for the state of Pará, extends distribution ~1000 km eastward in the Brazilian Amazon, from the easternmost published record in the Rio Madeira (Heyer 1977).

Scinax boesemani. Laranjal Stream, secondary vegetation. 28 October 1997. MPEG 8819. Arauá River, in aquatic vegetation. 22 June 1997. MPEG 8820. A species of wide distribution in the Brazilian Amazon and Guyana region, it has been recorded in the Belém region (Crump 1971).

Leptodactylidae

Hydrolaetare schmidti. Mouth of the Laranjal Stream, "várzea." 6 April 1998. MPEG 8790. First record for state of Pará, extends distribution ~1000 km eastward in the Amazon basin, from the easternmost published record in the Rio Madeira (Heyer 1977).

Leptodactylus pentadactylus. Edge of the Curuá River, in an area of secondary vegetation. 18 October 1997. MPEG 8785. Edge of the Laranjal Stream, secondary vegetation. April 1998. MPEG 8786–87. Edge of the Arauá River, secondary vegetation. 22 June 1997. MPEG 8788. Edge of the Curuá river, in primary forest. 22 April 1998. MPEG 8789. A species of broad distribution in Central and South America, which has been recorded in Belém (Crump 1971).

Leptodactylus rhodomystax. Laranjal Stream, in primary forest. 30 July 1997. MPEG 8823. Species of general occurrence in the Amazon basin; this record confirms its presence at almost all sites researched in the region.

Pipidae

Pipa pipa. Camuin channel, "igapó." 28 October 1998. MPEG 8791–94. Laranjal Stream, in aquatic vegetation. October 1998. MPEG 8795–98. Laranjal Stream, in aquatic vegetation. 4 April 1998. MPEG 8799–800. Species known from state of Pará from Belém, Bragança and Marajó region (Trueb and Cannatella 1986); the record reported herein is along a range margin in the Amazon River drainage.

Ranidae

Rana palmipes. Laranjal Stream, "várzea." 6 April 1998. MPEG 8776–84. The species has a broad distribution in northern South America, but published data are lacking for most of Brazilian Amazon (Miranda-Ribeiro 1923; Hillis and de Sá 1988). This record confirms its occurrence close to the mouth of the Amazon River.

Bufonidae

Bufo castaneoticus. Edges of the Curuá River, primary forest. February 1996. MPEG 8110–12. Edges of the Curuá River, primary forest. August 1996. MPEG 8235-36, MPEG 8238-41. Published data for the distribution of this toad are restricted to the type locality in the species description (Caldwell 1991). Recent inventories, however, demonstrated the species occurrence in four other Brazilian sites, in the state of Rondônia, Amazonas, and Pará (Caldwell, unpubl. data). Record reported herein is about 183 km north of the published distribution for this anuran.

Acknowledgments.—We thank Reginaldo A. T. Rocha for assistance in the field, David C. Oren for reviewing the manuscript, and CAPES for a fellowship to J. A. R. Bernardi.

In the course of conducting herpetological surveys for the Plumas and Tahoe National Forests, eight new county records for reptile species were noted. These are represented by six species not previously documented by museum records from Butte, Nevada, Plumas, or Yuba Counties.

The following eighteen museum collections were queried for their holdings of Butte, Nevada, Plumas, and Yuba counties, California: AMNH, BYU, CAS, Chico State University, CM, FMNH, KU, LACM, MCZ, MVZ, SDSNH, SSU, TNHC, UMMZ, University of Nevada (Las Vegas), UNR, USNM, and UTA (museum codes follow Leviton et al. 1985). R. C. Drewes verified all specimen identifications.

Charina bottae (Rubber Boa). BUTTE CO: Plumas National Forest, Golden Trout Crossing Campground, opposite camp entrance S side of river (SE side of bridge), SE 1/4 of NE 1/4 Sec. 11, T20N, R7E (39°36'57.2"N, 121°08'31.7" W, 960 m elev.). 5 June 1998. J. A. Wilkinson and J. V. Vindum. CAS 205637–38. BUTTE CO: Plumas National Forest, Forest Rd 94, 2.25 km N (by road) of Fall River bridge, NE 1/4 of NE 1/4 Sec. 21, T21N, R7E (39°40'00.9"N, 121°11'35.5"W, 1067 m elev.). 9 June 1998. J. A. Wilkinson and J. V. Vindum. CAS 205711. YUBA CO: Plumas National Forest, Gold Run Creek, S bank at first large waterfall downstream from Forest Road 21N67Y, SE 1/4 of SE 1/4 Sec. 1, T20N, R8E (39°36'50.724"N, 121°01'29.1"W, 1158 m elev.). 9 July 1998. C. A. Reading and J. V. Vindum. CAS 205988. YUBA CO: Plumas National Forest, Forest Road 21N11, 2.9 km S (by road) of Forest Road 690, SW 1/4 of SE 1/4 Sec. 14, T20N, R8E (39°35'24.5"N, 121°02'57.5"W, 1183 m elev.). 1 October 1998. J. A. Wilkinson and K. D. Wiseman. CAS 206320.

Although Hayes and Cliff (1982) list *C. bottae* from Butte County, it is only known from a color slide in the first author's personal collection and from "scattered" sightings (Hayes 1999, pers. comm.). CAS 205637, 205638, and 205711 represent the first voucher specimens from Butte County.

Clemmys marmorata (Western Pond Turtle). NEVADA CO: Rt. 49, just N of North San Juan (ca. 610 m elev.). 5 May 1998. G. Frailey and M. M. Tierney. CAS 207045.

Diadophis punctatus (Ringneck Snake). PLUMAS CO: Plumas National Forest, road cut by Slate Creek Reservoir Dam (N side), SE 1/4 of SW 1/4 Sec. 2, T20N, R8E (39°36'52.6"N, 121°03'08.5"W, 1067 m elev.). 8 June 1998. J. A. Wilkinson and J. V. Vindum. CAS 205681. PLUMAS CO: Plumas National Forest, road cut on S side of Slate Creek bridge, NW 1/4 of NW 1/4 Sec. 11, T20N, R8E (39°36'44.3"N, 121°03'19.9"W, 1059 m elev.). 8 June 1998. J. A. Wilkinson and J. V. Vindum. CAS 205685. YUBA CO: Plumas National Forest, North Star-Slate Creek Reservoir road, 3.38 km NE (by road) of Quincy-La Porte Road, NW 1/4 of SW 1/4 Sec. 11, T20N, R8E (39°36'22.9"N, 121°03'42.3"W, 1158 m elev.). 8 June 1998. J. A. Wilkinson and J. V. Vindum. CAS 205667. YUBA CO: Plumas National Forest, Slate Creek above Slate Creek Reservoir, ca 100 m below 2nd dam, N side of creek, NW 1/4 of SW 1/4 Sec. 1, T20N, R8E (39°37'7.1652"N, 121°02'16.1988"W, 1091 m elev.). 29 September 1998. J. A. Wilkinson and K. D. Wiseman. CAS 206298.

Hayes and Cliff (1982) stated that in adjacent Butte County, *D. punctatus* is infrequent above 700 m elevation, but may extend to 1000 m. All specimens from Plumas and Yuba counties were collected from above 1000 m (between 1059 m and 1158 m).

Elgaria coerulea (Northern Alligator Lizard). YUBA CO: Plumas National Forest, Forest Road 35, 2.57 km E (by road) of Forest Road 04, SE 1/4 of NE 1/4 Sec. 22, T20N, R8E (39°34'45.8"N, 121°03'47.1"W, 1090 m elev.). 18 June 1998. M. S. Koo and J. V. Vindum. CAS 205714. YUBA CO: Plumas National Forest, Brushy Creek at Forest Road 35, near jct. of Forest Road 35 and Forest Road 21N11.4, NW 1/4 of SE 1/4 Sec. 23, T20N, R8E (39°34'32.7"N, 121°02'49.4"W, 1097 m elev.). 18 June 1998. M. S. Koo and J. V. Vindum. CAS 205716. YUBA CO: Plumas National Forest, Slate Creek above Slate Creek Reservoir, NW 1/4 of SE 1/4 Sec. 1, T20N, R8E (39°37'1.776"N, 121°02'21.624"W, 1103 m elev.). 28 September 1998. J. A. Wilkinson and K. D. Wiseman. CAS 206290. YUBA CO: Plumas National Forest, Slate Creek, above Slate Creek Reservoir (NE side), NW 1/4 of SE 1/4 Sec. 1, T20N, R8E (39°37'5.808"N, 121°02'19.356"W, 1103 m elev.). 28 September 1998. J. A. Wilkinson and K. D. Wiseman. CAS 206291. YUBA CO: Plumas National Forest, Forest Road 35, 1.77 km NE (by road) of Forest Road 20N68, SW 1/4 of SE 1/4 Sec. 24, T20N, R8E (39°34'20.6"N, 121°01'48.2"W, 1189 m elev.). 1 October 1998. J. A. Wilkinson and K. D. Wiseman. CAS 206319.

Lampropeltis getula (Common Kingsnake). YUBA CO: Marysville Road, 0.80 km N (by road) of Loma Rica Road (39°20'03.7"N, 121°20'21.4"W, 311 m elev.). 6 June 1998. J. A. Wilkinson and J. V. Vindum. CAS 205665.

Thamnophis couchii (Sierra Garter Snake). YUBA CO: Plumas National Forest, Brushy Creek at Forest Road 35, 100 m downstream from Forest Road 35, NW 1/4 of SE 1/4 Sec. 23, T20N, R8E (39°34'30.576"N, 121°02'49.2"W, 1097 m elev.). 19 June 1998. M. S. Koo and J. V. Vindum. CAS 205719. YUBA CO: Plumas National Forest, Gold Run Creek, ca. 300 m upstream of the end of Forest Road 21N67Y, NE 1/4 of NW 1/4 Sec. 7, T20N, R9E (39°37'13.728"N, 121°00'56.052"W, 1288 m elev.). 9 July 1998. C. A. Reading and J. V. Vindum. CAS 205987. YUBA CO: Plumas National Forest, Gold Run Creek, ca. 200 m downstream of first large waterfall downstream from Forest Road 21N67Y, SE 1/4 of SE 1/4 Sec. 1, T20N, R8E (39°36'49.536"N, 121°01'37.92"W, 1143 m elev.). 9 July 1998. C. A. Reading and J. V. Vindum. CAS 205989. YUBA CO: Plumas National Forest, Slate Creek, above Slate Creek Reservoir (NE side), NW 1/4 of SE 1/4 Sec. 1, T20N, R8E (39°37'5.808"N, 121°02'19.356"W, 1103 m elev.). 28 September 1998. J. A. Wilkinson and K. D. Wiseman. CAS 206293. YUBA CO: Plumas National Forest, Slate Creek above Second dam, N bank, NW 1/4 of SW 1/4 Sec. 1, T20N, R8E (39°37'6.348"N, 121°02'9.564"W, 1091 m elev.). 29 September 1998. J. A. Wilkinson and K. D. Wiseman. CAS 206300. YUBA CO: Plumas National Forest, Slate Creek above dam upstream from Slate Creek Reservoir, SE side of tailings, SE 1/4 of SW 1/4 Sec. 1, T20N, R8E (39°36'59.22"N, 121°02'4.632"W, 1105 m elev.). 30 September 1998. J. A. Wilkinson and K. D. Wiseman. CAS 206301.

Prior to this report, only one specimen of *T. couchii,* collected in 1899, was allegedly recorded from Yuba County, but its exact locality remains difficult to pinpoint. Fitch (1940) lists the specimen (CAS-SU 6309) from Strawberry Valley, Yuba County. The Stanford catalog (now at CAS) describes the original locality as "near Strawberry Valley, Butte and Sierra Co. line". However, Butte and Sierra counties do not share a common border. The Butte-Yuba county border is within a kilometer of the town of Strawberry Valley. Because the locality description indicates that the specimen is from "near Strawberry Valley," it is not clear if the specimen came from Butte or Yuba County. The current documentation of six specimens clearly establishes the occurrence of *T. couchii* in Yuba County.

Acknowledgments.—We thank the staff of the above mentioned museums for supplying collection records. Field work was funded by a Challenge Cost-Share Agreement between CAS and the U.S. Department of Agriculture, Forest Service, Tahoe National Forest and Plumas National Forest (CCS-05-98-17-123) as well as generous donations to the Department of Herpetology, CAS, from Emily Date, Malcolm Miller, and Mr. and Mrs. Richard Dumke. We also thank Marilyn Tierney, Tahoe National Forest, and Kristina Hopkins, Plumas National Forest, for their support and expertise.

New Records of Snakes from Argentina

ALEJANDRO R. GIRAUDO
Instituto Nacional de Limnología (INALI-CONICET)
José Maciá 1933, (3016), Santo Tomé, Santa Fe, Argentina
e-mail: inali@arcride.edu.ar

Several checklists and general revisions of Argentine snakes have been published since 1861 (Abalos and Mischis 1975; Berg 1898; Burmeister 1861; Cei 1986, 1993; Koslowsky 1898; Serié 1921, 1926; Williams and Francini 1991). However, knowledge about the composition and distribution of the ophidiofauna from many areas of the country are incomplete. During the last ten years, a survey of snakes of northeastern Argentina was been conducted by the author, collecting new material during one hundred field trips and reviewing the herpetological collections in Argentine museums. As a result, significant enhancement of distributional data for several species were obtained as well as some new records for some Argentine provinces and for the country.

All records are based on specimens deposited in the following herpetological collections: Museo Argentino de Ciencias Naturales, Buenos Aires (MACN), Fundación Miguel Lillo, Tucumán (FML), Universidad Nacional de Misiones, Posadas, Misiones (UNAM), Centro de Investigaciones Ecológicas Subtropicales del Parque Nacional Iguazú, Iguazú, Misiones (CIES), Centro Nacional de Iología, Buenos Aires (CENAI), and Colección Félix de Azara, Consejo Nacional de Investigaciones Científicas y Técnicas, Buenos Aires (CFA). The two last collections were recently deposited in the MACN. Identifications were verified primarily by G. Scrocchi and S. Kretzschmar (Fundación Miguel Lillo, Tucumán, Argentina), and F. Franco (Instituto Butantan, São Paulo, Brazil), kindly verified the specimen of *Clelia quimi*. The following abbreviations were used: TOL, total length; SVL, snout-vent length; and TL, tail length.

LEPTOTYPHLOPIDAE

Leptotyphlops munoai. MISIONES PROV: CAINGUÁS DEPARTMENT: Dos de Mayo. J. Soroka (MACN 32050, 126 mm TOL, 6 mm TL; MACN 32051, 171 mm TOL, 8 mm TL); CANDELARIA DEPARTMENT: Loreto, Estación Experimental del INTA. September 1933. A. Ogloblin (MACN 1033). First province records and the northernmost record for the species; extends range ca. 150 km air line N from the nearest known record in Corrientes Province (Orejas Miranda 1961; Miranda and Tio Vallejo 1985; Williams and Francini 1991; Cei 1993). CORRIENTES PROV: ITUZAINGÓ DEPARMENT: Estancia Puerto Valle. 1 September 1994. A. Giraudo (CFA 726, 132 mm TOL, 8 mm TL). Specimen was caught in a flooded area by the closing of Yacyreta dam. Species had been reported from Corrientes Province by several authors (Miranda and Tio Vallejo 1985; Williams and Francini 1991; Cei 1993), but they did not report a specific locality, repository or specimen catalogue number. Recently, Alvarez et al. (1996), did not include this species in their list of herpetofauna of Corrientes.

COLUBRIDAE

Clelia quimi. MISIONES PROV: CAPITAL DEPARTMENT: Posadas City, 180 m elev. 27 April 1995. R. Stetson Jr. (CUNAM 323, an adult male, 955 mm TOL, 186 mm TL). First record for Argentina and the southernmost record for the species; extends range ca. 700 km air line SW from the nearest populations known in the state of Santa Catarina, Brazil (Franco et al. 1997). Species was known from highlands in the Southern Plateau, Atlantic Plateau and Central Plateau of Distrito Federal and the states of Espírito Santo, Minas Gerais, Sao Paulo, Paraná and Santa Catarina, Brazil (Franco et al. 1997).

Liophis frenatus (False Coral Water Snake) MISIONES PROV: CAPITAL DEPARTMENT: Posadas City. 8 January 1954. A. Scarso (CENAI 1156, an adult female 530 mm TOL, 77 mm TL). Second record for the province and for Argentina. Extends range ca. 300 km air line south from the nearest known Argentinian record at Iguazú Falls (Giraudo et al. 1993). Also reported from the Paraguayan Paraná islands, flooded by the closing of Yacyretá dam, on the border with Argentina (Alvarez et al. 1995; Aquino et al. 1996).

Oxyrhopus clathratus (False Coral Snake). MISIONES PROV: CAINGUÁS DEPARTMENT: Dos de Mayo. March 1972. A. Barrio, F. Contino and Piorot (CENAI 3187, an adult); IGUAZÚ DEPARTMENT: two specimens from Arroyo Urugua-í, 30 km E Puerto Bemberg. 9 and 30 November 1960 respectively. W. H. Partridge (MACN 12762, male, 347 mm TOL, 65 mm TL; and MACN 12761, female 399 mm TOL, 70 mm TL); GENERAL M. BELGRANO DEPARTMENT: Cabureí, ca. 5 km E Iguazú National Park. 1 May 1995. A. Jhonson (CIES 227, male, 623 mm SVL) and San Antonio, Reserva Natural Estricta. 16 November 1995. A. Arce (CIES 249, female, 394 mm TOL, 67 mm TL); SAN PEDRO DEPARTMENT: Tobuna. February 1952. W. H. Partridge (MACN 12642, a female, 1011 mm TOL, 163 mm TL). Species was known in Argentina only from Barracón, Misiones (now Bernardo de Irigoyen), the unique precise locality published by

Cranwell (1943). Other authors had mentioned this species for "Misiones," probably based on Cranwell's record (Abalos and Mischis 1975; Williams and Francini 1991; Cei 1993), but did not report new specific localities. The five localities reported herein extend the known range of the species in Argentina and Misiones ca. 80 km northwest and 135 km southwest.

Oxyrhopus petola (Calico Snake or False Coral Snake). MISIONES PROV: IGUAZÚ DEPARTMENT: Ten specimens from the Iguazú National Park, Secional Yacuí. 24 January 1995 (CIES 211); Arroyo Santo Domingo and Ruta Nacional 101. July 1993. S. Acosta (CIES 151); Campamento Yaguareté. May 1993. S. Acosta (CIES 159, female, 300 mm TOL, 61 mm TL); Puerto Canoas. 4 November 1994. S. Chediack (CIES 210); Seccional Timbó. 29 March 1994. J. Calo (CIES 189, female, 870 mm TOL, 240 mm TL); Control de Acceso: 20 November 1993. S. Acosta (CIES 174, male, 340 mm TOL, 78 mm TL). 14 August 1997. A. Caradonna (CIES 301). 29 March 1998. J. Zocatelli (CIES 302); Acceso a Cataratas: 2 March 1995. D. De La Torre (CIES 215). 16 June 1996. S. Acosta and F. Del Castillo (CIES 273). Species was known in Argentina from three specimens collected in the Iguazú National Park (Giraudo et al. 1993). Specimens reported herein extend the known range ca. 30 km east of the previous records.

Phalotris reticulatus. CORRIENTES PROV: GENERAL SAN MARTÍN DEPARTMENT: Colonia Carlos Pellegrini. Ince Apóstol (MACN 36085, unknown sex, 239 mm TOL, 19 mm TL). Lema (1984) reported this snake from northeastern Misiones Province, but a precise locality, repository and specimen catalogue number was not given. This is the first province record, and extends range ca. 350 km southwest from the closest locality in Misiones. These are also the first voucher specimens for Argentina.

Pseudablabes agassizii. CHACO PROV: MAYOR LUIS FONTANA DEPARTMENT: Coronel Dugraty. 2 October 1968. Collector unknown (CENAI 2614, female, 458 mm TOL, 101 mm TL); FRAY J. SANTA MARIA DE ORO DEPARTMENT: Zuberbuhler. 20 September 1967. A. Galarza (CENAI 2380, female, 526 mm TOL, 115 mm TL). MISIONES PROV: CANDELARIA DEPARTMENT: Santa Ana. 1901. A. Llamas (MACN 1523); APOSTOLES DEPARTMENT: San José. 22 November 1968. Collector unknown (CENAI 2594, female, 395 mm TOL, 87 mm TL); Misiones without specific locality. 1915. Doello Jurado (MACN 2724). SANTIAGO DEL ESTERO PROV: COPO DEPARTMENT: Reserva El Copo. 1988 (MACN 33551). First record for both Provinces and the northernmost records for Argentina; extend range ca. 550 km northeast (Misiones record) and 400 km northwest (Santiago del Estero record) from the nearest records in Santa Fe, Entre Ríos and Córdoba provinces (Gallardo 1982; Viñas 1985; Viñas et al. 1989; Williams and Francini 1991).

Pseudoboa haasi. MISIONES PROV: GENERAL BELGRANO DEPARTMENT: San Antonio, Ruta Nacional 101 and Arroyo Tigre. 20 March 1995. A. Arce (CIES 257, male, 1288 mm TOL, 290 mm TL). Known in Argentina from two specimens collected in northern Misiones Province (Giraudo 1992; Morato et al. 1995). Extends the range ca. 30 km southeast from the nearest known locality, and is the third specimen known from Argentina.

Pseudoeryx p. plicatillis. FORMOSA PROV: PILCOMAYO DEPARTMENT: Pilcomayo. Collector unknown (MACN 4166, female, 490 mm TOL, 11.4 mm TL). Species was cited by several authors from the provinces of Chaco, Corrientes, Formosa and Misiones (Berg 1898; Koslowsky 1898; Serié 1921, 1936; Williams and Francini 1991; Cei 1993), but all records lack a precise locality, repository, and specimen catalogue number. Probably for this reason, Williams and Francini (1991) suggested that the presence of this species needed confirmation. The Pilcomayo specimen represents the first precise locality published for this snake in Argentina.

Furthermore, three additional specimens were recorded in Paraguay, 1 km airline east from southern Formosa Province (Argentina), as follows: ÑEEMBUCÚ DEPARTMENT: Pilar City. 10 March 1995. A. Contreras (CFA 820 and CFA 821, two specimens, females, 794 mm and 807 mm TOL, 108 mm and 114 mm TL, respectively); Yatayty, 5 km E from Pilar. 1 June 1994. A. Giraudo (FML 06499, male, 790 mm TOL, 172 mm TL). These records are the southernmost known for the species, and the first with precise locality.

Sibynomorphus ventrimaculatus (Ñandurirey). CORRIENTES PROV: ITUZAINGÓ DEPARTMENT: Estancia Puerto Valle. 21 January 1990. E. Franke (CFA 105, unknown sex, 412 mm SVL); SANTO TOMÉ DEPARTMENT: Santo Tomé. April 1993. S. Gonzalez (CFA 409, male, 509 mm TOL, 116 mm TL). Second and third localities recorded for the province of Corrientes, and extends range ca. 75 km south and 65 km airline west from the previous record (Lions and Alvarez 1996).

Acknowledgments.—The curators of the museums mentioned above, Gustavo Carrizo, Gustavo Couturier, Beatriz Alvarez, Gustavo Scrocchi, Laura Malmierca, Karina Schiaffino, generously permitted me to use their collections. CONICET (Consejo Nacional de Investigaciones Científicas y Técnicas) supported my investigations. I thank Raúl Abramson, Sergio Acosta and the others guards from the Iguazú National Park for their assistance during field work.

New Distribution Records from the Wisconsin Herpetology Atlas Project, 1998

GARY S. CASPER
Section of Vertebrate Zoology, Milwaukee Public Museum
800 West Wells Street, Milwaukee, Wisconsin 53233, USA
e-mail: gsc@mpm.edu

Collected here are fifteen new county records for Wisconsin, USA. All material is deposited at the Milwaukee Public Museum (MPM), and has been verified by Robert W. Henderson. MPM-H numbers denote specimen collections, MPM-P numbers denote photographic vouchers.

Ambystoma maculatum (Spotted Salamander). Sheboygan Co: SW 1/4 Sec. 29, T15N R20E, along Rt. U, one mile south of Hilltop Lane, under log in mixed hardwood forest along Greenbush Trails, Kettle Moraine State Forest. 10 May 1997. Christine Stanke. MPM-P 652. New county record within expected range, further documenting this species within the southward extension of the northern hardwood forest along glacial moraines in southeastern Wisconsin (Casper 1996). Ca. 65 km from nearest previously mapped location (Vogt 1981).

Necturus maculosus (Common Mudpuppy). Eau Claire Co: Chippewa River in Putnam Park, Eau Claire, NW 1/4 Sec. 29, T27N R10W. 1 May 1997. Eric Hopper. MPM-H 30341. Caught while fishing. New county record within expected range (Casper 1996). Ca. 45 km from nearest other record in Chippewa River basin (Vogt 1981). Marquette Co: Sec. 35, T17N R10E, Mecan River at upper dike road bridge. 16 September 1997. Jerry Reetz. MPM-P 642. New county record within expected range (Casper 1996). Ca. 15 km from nearest mapped Fox River watershed locality (Vogt 1981).

Pseudacris c. crucifer (Northern Spring Peeper). Racine Co: Buck's Trail Archery Club, S side of Burlington, N 1/2 Sec. 5, T2N R19E. 16 April 1997. Beth Goeppinger. MPM Herpetology Audio Tape 4-16-97. New county record within expected range (Casper 1996). Accredits reported observations from Racine County Wisconsin Frog and Toad Survey Routes (Mossman et al. 1998)

Hyla chrysoscelis (Cope's Gray Treefrog). Kenosha Co: Bong State Recreation Area, T2N R20E. 25 April 1990. Beth Goeppinger. MPM-P 616–18 with audio tape on file. New county record within expected range (Casper 1996). Accredits reported observations from Kenosha County Wisconsin Frog and Toad Survey Routes (Mossman et al. 1998).

Chelydra serpentina (Common Snapping Turtle). Winnebago Co: Neenah Slough at 36 Jewlers Drive, SW 1/4 Sec. 33, T20N R17E. 25 July 1997. Randy Grimes. MPM-P 632. New county record within expected range (Casper 1996). Green Lake Co: NW 1/4 Sec. 17, T17N R12E. 13 August 1997. Jerry Reetz. MPM-P 640; S 1/2 Sec. 8, T17N R12E, jct South Road and Marsh Road on section line, Sucker Creek nearby. 9 June 1998. Jerry Reetz. New county record within expected range (Casper 1996).

Emydoidea blandingii (Blanding's Turtle). Rock Co: SW 1/4 Sec. 3, T4N R14E, 1.1 miles E of Rt. KK on Rt. N. 14 June 1998. Jeff Riedi. MPM-P 645. New county record within expected range (Casper 1996).

Graptemys geographica (Common Map Turtle). Kenosha Co: Powers Lake, NE 1/4 Sec. 18, T1N R19E. 18 August 1994. Mathew G. Bolek. MPM-H 29588. Netted from boat, six others observed. New county record (Casper 1996). Part of East Branch of Nippersink Creek within Fox River watershed, and ca. 26 stream km from nearest Fox River records in Lake County, Illinois (FMNH 22080; Smith 1961).

Apalone spinifera (Spiny Softshell). Dodge Co: Crawfish River at Old Rt. 73, SW 1/4 Sec. 6, T10N R13E. 8 June 1997. Ben Lenz and Hansel Hallman. MPM-P 630. New county record within expected range (Casper 1996). Extends records from Rock River watershed north by ca. 45 km (Vogt 1981).

Elaphe v. vulpina (Western Fox Snake). Ozaukee Co: Thiensville, NE 1/4 Sec. 15, T9N R21E, Rt. 57, south of Highland Road. 9 June 1993. Lon Carriveau. MPM-H 30350. Roadkill. New county record (Casper 1996). Additional record for previously reported range gap in east-central Wisconsin (Vogt 1981).

Lampropeltis t. triangulum (Eastern Milk Snake). Winnebago Co: Sec. 10, T17N R14E. 26 May 1997. Jerry Reetz. MPM Herpetology-P 641. New county record within expected range (Casper 1996). Continues to fill prior range gap in east-central Wisconsin, with this record ca. 30 km from nearest previously mapped location (Vogt 1981).

Storeria o. occipitomaculata (Northern Redbelly Snake). Outagamie Co: Mosquito Hill Nature Center, New London, NW 1/4 of SE 1/4 Sec. 17, T22N R15E. 23 May 1996. James S. Anderson. MPM-P 620. New county record within expected range (Casper 1996). Green Lake Co: NW 1/4 Sec. 31, T17N R12E. 29 April 1997. Jerry Reetz. MPM-P 639. New county record within expected range (Casper 1996).

Storeria dekayi (Brown Snake). Pepin Co: jct Wisconsin Rts. 25 and 10, NW 1/4 Sec. 20, T25N R13W. 5 July 1997. David Linderud. MPM-P 631. New county record within expected range (Casper 1996).

e-mail: patricio@copetel.com.ar

The present note provides six new records for the Patagonian herpetofauna and La Pampa Province in Argentina. Distributional records are two new localities of the genus *Liolaemus,* one confirmation for the eastern distribution of a species of *Liolaemus,* a new provincial record for a species of *Pristidactylus,* new southernmost records for a species of *Phymaturus* (considered endemic to the Somuncura Plateau) and a colubrid snake (*Pseudotomodon trigonatus*). All species were verified by Laura Vega. Voucher specimens are deposited at the Universidad Nacional de Mar del Plata collection (UNMdP) and the Centro Regional de Investigaciones y Transferencia Tecnologica La Rioja collection (CRILaR).

IGUANIDAE

Pristidactylus scapulatus. RIO NEGRO: Dpt. 25 de Mayo, 77 km NW Sierra Colorada (2 km S Esperanza) on the roadside of Provincial Rt. 68 (40°26'S, 68°22'W). 2 February 1999. P. J. Bellagamba, J. A. Schulte II, and F. B. Cruz. CRILaR PT 4810. First record for the province. Cei (1986) cites this species as occurring in Neuquén and Chubut provinces, but not from Rio Negro. The specimen was collected on small rock boulders (less than a meter high) in sympatry with *Diplolaemus* var. *altopatagonica, Liolaemus melanops, L. bibroni,* and *Homonota darwinii.* A second specimen (UNMDP 525) was found on rock boulders on the roadside of provincial road 13 (42°26'S, 69°41'W) in Chubut Province, being sympatric with *Liolaemus petrophilus, L. rothi,* and *Homonota darwinii.*

Phymaturus somuncurensis. RIO NEGRO: Dpt. 25 de Mayo, 43 km N Moligüe on rock boulders near Provincial Rt. 76 (41°35'S, 69°22'W). 1 February 1999. P. J. Bellagamba, J. A. Schulte II, and F. B. Cruz. CRILaR FBC 106–111. This species was considered endemic to the Meseta Somuncura (Cei 1986); however, the present record is at least 100 km west of the Somuncura foothills, and the first for Department 25 de Mayo. *Liolaemus elongatus, Diplolaemus* var. *altopatagonica,* and *Homonota darwinii* were also found in this type of habitat.

Liolaemus xanthoviridis. CHUBUT: Dpt. Biedma, Peninsula de Valdéz, Bahia Fracaso Beach (42°25'S, 64°07'W). 29 January 1999. A. Marcus, P. J. Bellagamba, J. A. Schulte II, and F. B. Cruz. CRILaR PT 4773. First record for Peninsula de Valdiz and northernmost locality. Cei (1986) cites this species from Chubut River (in the south) to Punta Clara. Halloy et al. (1998) mention Laguna de los Indios as the northern limit of this species. This record extends the range 70 km north of the preceding citations and is a new department record.

Liolaemus cuyanus. LA PAMPA: Dpt. Limay Mahuida, 88 km W La Reforma on the roadside of Road 20, (37°39'S, 67°11'W). 3 February 1999. P. J. Bellagamba, J. A. Schulte II, and F. B. Cruz. CRILaR FBC 0067-69. First record for the province. Tiranti and Avila (1997) do not mention this species occurring in the province and one of the authors (S. Tiranti, pers. comm.) mentions that no observations were made of species not on their checklist in his most recent field trips. Habitat of this species was scrub vegatation in Monte desert found in sympatry with *Liolaemus darwinii, Liolaemus gracilis,* and *Cnemidophorus longicaudus.*

Liolaemus kriegi. CHUBUT: Dpt. Cushamen, 25 km S of Moligüe, on rock boulders on the roadside of Provincial Rt. 13 (42°04'S, 69°31'W). 1 February 1999. P. J. Bellagamba, J. A. Schulte II, and F. B. Cruz. CRILaR PT 4848–50. This record confirms the eastern distribution for the species (Cei 1986), but is more than 100 km to the south of Ing. Jacobaci (the easternmost locality) and 20 km south of the northern border of Chubut Province. Cei (1986) mentions the geographic range of this lizard as the occidental region of Rio Negro Province to the border of Chubut, but the presence of this species in the province of Rio Negro remains unclear.

COLUBRIDAE

Pseudotomodon trigonatus. CHUBUT: Dpt. Florentino Ameghino, Cantera las lajas 20 km S Punta Tombo, 1 km E Provincial Route 1 (44°07'57"S, 65°26'W). 27 January 1999. P. J. Bellagamba, J. A. Schulte II, and F. B. Cruz. UNMDP 524. Cei (1986) mentions Puerto Madryn as the southern limit for the species. This record is the southernmost locality and extends the range of this species 120 km farther south than any previously known locality. The type of habitat was a meteorized rocky hill (lajas), where *Homonota darwinii* was also captured.

Acknowledgments.—The authors thank Alicia Marcus and Roberto Lech for assistance in the field and their generous hospitality while in Chubut. We are grateful to Laura Vega for identification of specimens. This work was partially supported by a grant from the National Science Foundation (BSR-9318642 to J. B. Losos, K. de Queiroz, and A. Larson). This note was prepared while the second author was supported by a National Science Foundation Fellowship.

This monograph, devoted to the reptilian orders Chelonii and Squamata of the Iberian Peninsula and Balearic islands, is the tenth in the series *Fauna Ibérica*, the proceedings of a project aimed at acquiring basic zoological, and especially systematic, information about the Ibero-Balearic area.

The book begins with an introduction to the biology of reptiles, including classification, morphology, natural history, and study methods. The body of the book consists of systematic accounts of 26 genera and 47 species of reptiles (in alphabetical order within families). This is followed by a very important list of 2303 bibliographic references, and finally a partially annotated list of synonyms and combinations, and a short glossary.

The same format is used for each species, with each account consisting of sections devoted to (1) scientific name, senior synonym and common name, (2) external morphology, (3) skeleton, (4) sexual dimorphism, (5) genetic data, (6) variation, (7) distribution, (8) fossil record, (9) habitat, (10) activity, (11) food habits, (12) predators, (13) parasites, (14) reproduction and growth, (15) population structure and dynamics, and (16) conservation. For each species, one or more judiciously selected black and white drawings by Pedro Salgado and a distribution map (and often a comparative table of food habits in different countries) complete the account.

Including the coordinator, eight authors shared editing duties: A. C. Andreu and L. F. López-Jurado for the nine species of Chelonii, A. Salvador for the seven species of Iguania, Amphisbaenia, and Scleroglossa (except the Lacertidae), V. Pérez-Mellado for the 18 species of Lacertidae, A. Bea, Fl. Braña, P. Galán, and J. M. Pleguezuelos for the 13 species of Serpentes.

The goal of the editors was to publish a work "intermediate between a technical book and a popular field guide" (MNCN-CSIC 1998). I think that they have attained their objective, however, I do have some critical observations of this otherwise enjoyable book. These comments concern both major and minor points of detail, distribution maps, taxonomy, and systematics.

The first error, undoubtedly due to the delay of printing, appears at the top of p. 4, where the suggested citation format of the book is given as "Salvador, A. (Coordinador), 1997... " instead of 1998, the date of publication which figures at the bottom of the same page. The same date is erroneously mentioned on page 152 in connection with *Chalcides bedriagai cobosi* nom. nov., authorship of which should correctly be cited as Valverde, 1998.

At a time when molecular studies have proven their utility in systematics, it is unfortunate that the "collection, preservation and methods of study" chapter completely omits aspects of tissue collection. Further, the only recommended preservatives are those containing formaldehyde, which causes disastrous effects on both the quantity and quality of the DNA that can be extracted from samples. Alternative methods include both cryopreservation and ethanol or fluid buffer preservation (e.g., Dessauer et al. 1996; Sibley and Ahlquist 1981).

As presented in the book, bibliographic citations always appear to refer to the original literature rather than to secondary sources or other authors' interpretation of subsequent citations. This, however, was clearly not the case, for example, in the chapter devoted to *Lacerta vivipara*, where V. Pérez-Mellado writes on p. 233: "A notable enzymatic variability exists within the European populations (Grenot and Heulin, 1990)." The original sentence of Grenot and Heulin (1990)—whose article has nothing to do with enzymes—is (p. 17): "Although an important enzymatic variability was recognized between populations (Salvidio et al. 1990; Bea et al. 1990), this species...." This article of Grenot and Heulin (1990) is again misquoted two times on p. 240, once with respect to the distribution of oviparous populations of *Lacerta vivipara*, referring to Fig. 1b from Heulin and Guillaume (1989), and the other about the different forms of egg membranes, a subject that is not mentioned in Grenot and Heulin (1990)! It would have been better to quote Heulin (1988), Heulin (1990, not in the bibliographic list) and Heulin et al. (1992). In the same section, on p. 242, an article of Spitz (1971), devoted to *Lacerta viridis* and *Lacerta agilis*, erroneously serves as reference for the area of the home range of *Lacerta vivipara*! Finally, neither Nettmann and Rykena (1984) nor Goose and Castanet (1989) (cf. p. 229) assign the subspecies *Lacerta viridis prasina* to the Iberian peninsula (but rather *L. v. bilineata*). On the same page, a correctly referenced, but truncated quotation produces a misleading sentence. It is not: "*Lacerta viridis* possess *characteristic* bands for the GOT [nowadays called ATA] and the LDH-1 isoenzymes" but "*Lacerta viridis* possess bands (...) *diagnostic for the differentiation between L. viridis and L. trilineata.*"

Other misprints include 19 families instead of 18 as on Fig. 4 (p. 16); *Vipera latastei* instead of *V. latasti* (p. 269); and the number of erythrocytes must be 1,442,000/mm^3, not 442,000 (p. 411).

From my point of view, the distribution maps are the most problematic part of the book. The maps are without any names of Universal Transverse Mercator (UTM) squares (although the limits of provinces are drawn) and the only symbol used is a black dot (a separate symbol should at least have been provided for introduced populations).

We learn in the introduction that the maps were derived "from the atlas published by the Spanish Herpetological Association (1989), completed and in some cases corrected with subsequently published (Pleguezuelos, 1997) or original data, using UTM squares of 50 x 50 km." It is unclear why the former work is attributed to the "Asociación Herpetologica Española" instead of Martínez-Rica (1989) who is the volume's coordinator. On this basis, one might think that except for the difference of scale (the atlas of Pleguezuelos [1997] uses UTM squares of 20 x 20 km), the distribution maps of this book should be similar to those of Pleguezuelos (1997). This is true, however, for only ten species (turtles and terrestrial tortoises, *Lacerta perspicillata*, *Podarcis lilfordi*, and *P. sicula*). More often (26 species) one or a few dots have been added and/or removed. For nine species (*Chalcides bedriagai*, *C. striatus*, *Acanthodactylus erythrurus*, *Lacerta agilis*, *Blanus cinereus*, *Natrix maura*, *N. natrix*, and *Vipera latasti*) the differences are rather significant, and they are very important for *Emys orbicularis*, *Podarcis hispanica*, and

Coronella girondica. For *Podarcis hispanica*, the addition of 30 locality points is understandable as the map of Pleguezuelos (1997), because of data from Portugal confusing *P. hispanica* and *P. bocagei*, would suggest that these lizards are lusitanophobes. For *Coronella girondica*, I noticed eight added dots and 27 deleted ones, leading one to believe that this snake is severely threatened. On the other hand, the range of the European terrapin appears to be expanding as 28 points have been added and only one removed. There is no doubt that these differences are justified, but such differences should have been objectively discussed in the text, all the more because the European atlas (Gasc et al. 1997), published at about the same time, illustrates yet another set of distributions. Finally, the introduced population of *Podarcis pityusensis* in Barcelona, which is noted in the text, does not appear on the accompanying map. And, among the numerous regional atlases referenced in the bibliographic list, I didn't encounter the one of Basque country (Alvarez et al. 1985).

Systematics is supposed to have been the focus of the project upon which this book is based. After a good synthesis of the systematic position of the reptiles, with phylogenetic results at the familial level, a list of the 26 genera and 47 species is presented. The generic allocation of some species within the families Lacertidae and Colubridae has been the focus of discussion for many years. For the Colubridae, the problem is well reviewed on page 347, and J. M. Pleguezuelos explains that "more by convention than by conviction [he] continues to speak about the genus *Coluber* on the broad sense ..." but comparable problems are not dealt with in the case of Lacertidae (merely one sentence in the section devoted to *Lacerta perspicillata*). The reference used by V. Pérez-Mellado (p. 164) for higher order lacertid nomenclature is Arnold (1989), who recognized five genera in the Ibero-Balearic fauna: *Acanthodactylus, Algyroides, Psammodromus, Podarcis*, and *Lacerta* sensu lato, the last (a paraphyletic assemblage) including the subgenera *Lacerta, Thimon* (sic!), *Archaeolacerta*, and *Teira*. Since that time, numerous publications have tried to improve the systematic picture of the group (e.g., Bischoff 1991; Mayer and Benyr 1994; Olmo et al. 1990, 1992). To my knowledge, the last important contribution is that of Mayer and Bischoff (1996), which validates the genera *Zootoca* (with only the species *Z. vivipara*), *Timon* (with *T. lepidus, T. pater*), and *Teira* (*T. perspicillata*). For this last species, Bons and Geniez (1996) have also proposed *Scelarcis perspicillata*. Without reference to an universally accepted generic concept, the taxonomy at this level involves a good deal of subjectivity and permits the authors to take a particular position, but I feel that, in a book focused on systematics, a more explicit discussion of the controversies involved should be presented.

A book such as this presents a real opportunity to put the nomenclature of the species and subspecies occurring in a country in order. Specific changes are very rare and generally do not pose a problem. Nevertheless, I have noted the following ones. *Lacerta aranica* and *L. aurelioi* are not dealt with in a separate chapter, but are discussed in a section devoted to *L. bonnali,* with the conclusion that "it is necessary to make a deeper study of those populations...before accepting without reserve the specific separation and the proposed subspecies...." (p. 195). However, *Lacerta aranica* and *L. aurelioi* figure as full species in the final taxonomic list. On the contrary, *Lacerta cyreni*, recently described by Arribas (1996), is discussed in the section devoted to *Lacerta monticola*, with the conclusion that "The arguments presented do not seem convincing.... These results have to be compared with future works to permit the definitive acceptance or rejection of such taxonomic novelties." (p. 210). It remains in the final taxonomic list as a subspecies of *Lacerta monticola*. The bases for these differences in treatment are unclear. Concerning *Lacerta viridis*, it would have been best to precede the nomenclatural change by citing the possible revalidation of the name *L. bilineata* recently made by Amann et. al. (1997).

The subspecific changes are relatively numerous. The real taxonomic novelty concerns *Chalcides bedriagai cobosi* nom. nov., a replacement name for *C. b. albaradae* Valverde 1968, proposed in accordance with the code of ethics (recommendation no. 3, Appendix A) of the International Code of Zoological Nomenclature (Ride et al. 1985). Most of the other changes are discussed and confirm the opinion expressed by earlier works (for instance the placing in synonymy with their respective nominal subspecies of *Eretmochelys imbricata bissa, Dermochelys coriacea schlegelii, Hemidactylus turcicus spinalis*, or *Algiroides marchi niethammeri*). Some others, however, reflect only the opinion of the authors: for instance, A. C. Andreu and L.-F. Lopez-Jurado provide a description for and maintain the recognition of more or less disputable subspecies of *Emys* whose distributions are not precise. The same authors also have decided to conserve the subspecies *Testudo graeca graeca*. For the Lacertidae, V. Perez-Mellado has invalidated *Lacerta agilis garzoni, L. lepida iberica, Podarcis hispanica cebennensis,* and *P. h. sebastiani,* but prefers to maintain 24 valid subspecies of *Podarcis pityusensis* (the 23 of the list of Salvador [1986] plus *P. pityusensis canensis*), rather than the six recognized by the revision of Cirer (1987; Cirer *in* Pleguezuelos 1997).

In the case of *Podarcis hispanica*, I cannot accept the synonymy of *P. h. cebennensis* with the nominal subspecies on the basis of a superficial comparison based on the book of Pérez-Mellado and Galindo Villardon (1986) published at the same time as the description of this subspecies (Guillaume and Geniez 1986), and as a consequence not containing any samples of French *P. hispanica*. I have had the opportunity to express myself on the subject of this book and I maintain more than ever that "we may wonder whether all the calculations are of any help to...a preconceived taxonomy" (Guillaume and Pasteur 1989). Further, the citation of the name of the authors must be *P. h. cebennensis* Guillaume and Geniez *in* Fretey (ICZN [Ride et al. 1985], article 51, recommendation B).

Concerning *L. lepida iberica,* the work of Mateo et al. (1996), which is not cited, presents new evidence to prove that this subspecies is valid!

As "the series Fauna Ibérica joins a collection of monographs edited by specialists..." (MNCN-CSIC 1998), the fundamental question, beyond the systematic squabbles, is to define the taxonomic level (species, genus, family...) of a specialist. For instance, had José Antonio Mateo written the chapter on *Lacerta lepida* or Maria-Antonia Cirer that on *Podarcis pityusensis* (I intentionally cite people who prepared their theses on those respective taxa), the taxonomic conclusions would have been different.

A final remark concerning a minor taxonomic issue: the name of Valverde was put in brackets for *Algyroides marchi* (Valverde 1958). According to the ICZN (Ride et al. 1985), in pursuance of the articles 33 b ii ("a 'justified emendation' is the correction of an incorrect original spelling..." and 51 c i ("The use of parentheses applies only to changes in the name of the genus...; it is not affected...by emendation of the generic name..."), it seems to me that we may continue to write: *Algyroides marchi* Valverde, 1958, even if this author described *Algiroides marchi.*

To conclude, I think that, despite these criticisms, this book will, without any doubt, delight the Spanish and foreign hispanophilous reptile fanciers—although, for the general public, the addition of a photographic iconography could have been appropriate. This book provides a great service to professional herpetologists, who will appreciate the volume as a very good synthesis of current information, and because of its extensive and current list of bibliographic references.

Last but not least, volume 10 of "Fauna Ibérica" will probably become *the* reference for students working on the biology or ecology of Iberian reptiles and for administrators and managers concerned with the problems of conservation. I hope that other countries will follow such an example.

Field guides such as this can have enormous impact on the field of herpetology, as evidenced in North America by those written by Conant (1958) and Stebbins (1966). Compact sources of information, these kinds of books make information readily accessible for professionals and amateurs alike. More importantly, scientifically sound field guides promote scientific inquiry by delineating geographic and taxonomic questions. Branch's original *Field Guide to Snakes and other Reptiles of Southern Africa* (1988) was one of those important guides that allowed nonspecialists, really for the first time, a solid appreciation for the state of reptile systematics and distribution in southern Africa. The revised and updated guide, rewritten to address the great increase from 397 to 480 species, continues this extremely important contribution.

Having said that this is an important contribution, I am going to make a few minor criticisms. Book reviews never make you any friends, so I might as well. The first criticism is that I would have liked to see the standard formats of the first edition more improved than they have been. As in the first edition, technical keys are presented to the genus, then you are pretty much on your own to figure out what species is in hand. This can be reasonably difficult for the non-African specialist because of minor disorganization in the volume. One has to essentially construct a character matrix in one's head derived from the accounts, which are frequently not written in parallel among species within genus. Frankly, I was brought up on the Stebbins (1966) field guide for the western United States so I am probably biased towards the Houghton-Mifflin standard of noting 'key' characters, but the addition of these toeholds would have improved the utility of this volume considerably.

I am also not sure how the order of the accounts was arrived at; not alphabetical and seemingly not arranged by any measure of similarity. It would have been nice to have accounts arranged alphabetically, or by similarity clusters or with more extensive references to similar species and how to distinguish them. In addition, in an ideal world, field guides would have photographs and maps with the accounts, although I certainly understand the fiscal reasons for isolating photographs in signatures.

I was also confused by the checklist and common names list in an appendix. Because the species accounts in the body of the book are not arranged in alphabetical order and common names do not appear in the index, it is impossible to get from the checklist/common names list to the accounts. The index should have included these common names.

In summary, if you have any interest in the squamates of southern Africa, buy this book. Bill Branch has produced something that is useful and scientifically sound, something that not only reports on the state of knowledge about southern African reptiles, but also a volume that will focus research efforts.

Manny Rubio's study of rattlesnakes is aptly titled. Relying as much on photography as prose, Rubio, a photographer, deftly and effectively presents a portrait of rattlesnakes. In a foreword, William S. Brown suggests that Rubio's book could become the "semipopular replacement for Klauber's monumental tome on rattlesnakes" (xvi). It is difficult to disagree. The strengths Brown singles out in support of that claim are numerous and readily apparent. Drawing on the most recent research available, Rubio offers readable treatments of a diverse range of topics, presents a host of exceptional photographic illustrations, and disseminates crucial information on rattlesnake conservation. Certainly, he places rattlesnakes in their ecological and evolutionary contexts. Perhaps more uniquely, however, he also situates them within the various contexts of human thought, belief, and fear, allowing readers the opportunity to understand how our perceptions, misperceptions, and actions have become the single most significant factor in the continued existence of these animals.

Chapters competently cover the expected range of topics: rattlesnake origins, habitat, anatomy, sensory perception, feeding, physiology, thermal regulation, reproduction, movement, and envenomation. Rubio also addresses relevant topics that are a bit further afield, offering chapters on rattlesnake roundups, the economic and medicinal value of rattlesnakes, their role in folklore and religion, their function as crosscultural symbols, and, finally, their conservation. Although the book necessarily merits particular attention from those concerned with rattlesnakes, readers with even a casual interest in snakes, conservation, or anthropology will find it of interest. In addressing some of the nonscientific, nontechnical dimensions of his subject, however, Rubio does not diminish the usefulness of this study. He admirably achieves his goal of presenting a thorough, semitechnical introduction to rattlesnakes, thoughtfully including the exact combination of basic and supplementary information such a text should contain. In the main text, Rubio uses both Latin and common names for the species discussed, and in two appendices, provides species listings along with Spanish names for species indigenous to Spanish-speaking countries. Other useful features include an appendix of North American herpetological societies, a glossary, and an extensive bibliography.

Rubio's many photographs are exceptional for their clarity and vivid colors as well as for their illustrative effectiveness. A five-picture sequence succinctly demonstrates the distinctive facial markings of each subspecies of ridgenose rattlesnake (49), while a photograph of a subadult southern Pacific rattlesnake, *Crotalus viridis helleri*, taking a defensive posture against a California kingsnake, *Lampropeltis getula californiae*, provides an equally helpful complement to the text's description of that behavior (59). Among the many noteworthy photographs, several deserve particular mention. A selection of photos depicting aberrantly colored rattlesnakes gives some sense of how unusual these animals can appear. Included are oddities from patternless western diamondback and red diamond rattlesnakes (*Crotalus atrox* and *Crotalus ruber ruber*, respectively) to a hypererythristic, cranberry-colored Humantlan rattlesnake, *Crotalus scutulatus salvini*. Perhaps the most impressive photographs, however, are a sequence showing an immature banded rock rattlesnake, *Crotalus lepidus klauberi*, feeding on a large banded centipede, *Scolopendra polymorpha* (73, 76).

Rubio's very personal document is clearly inspired by a genuine affection for his subject. Not surprisingly, his approach places the book squarely in two traditions: natural history essay and semi-technical science writing. That the personal and the scientific should collide at the point of conservation is both rhetorically and technically appropriate. Certainly, virtually every issue bearing on rattlesnake survival and diversity is directly dependent on human activities. Thus, while Rubio's tone is measured on matters of fact and science, it is indignant and sometimes scathing when assessing how people treat rattlesnakes. This is not, however, a defect. Rubio makes no claim to objectivity in addressing what he sees as the shortcomings of human behavior. Moreover, he takes great care to place human activities in the rattlesnake's ecological landscape—where, as for so many species, human activities loom very large. Like virtually all animals, rattlesnakes face a variety of dangers (120). Particularly when young, they are preyed upon by such creatures as ravens, skunks, roadrunners, and, occasionally, even bullfrogs and ants. Those that reach their second year remain subject to predation by coyotes, eagles, hawks, owls, javelinas, kingsnakes, feral pigs, badgers, indigo snakes, and even other, larger rattlesnakes. At all ages, but especially when young, they risk being struck by cars while crossing roadways. Inadequate hiding spots during temperature extremes or severe weather and insufficient small prey also take a heavy toll. First-year rattlesnake mortality can reach 80%, but a snake that reaches the age of four has a high probability of living ten or more years. Adults are large, have the advantage of well-established territories, and can accept a larger variety of prey items, while only a few animals (e.g., large hoofed stock animals, hogs, badgers, and alligators) will risk confronting them. Rubio emphasizes that humans pose the greatest threat to adult rattlesnakes, as they do to many top order predators.

Some of the dangers rattlesnakes face from humans result from something like good sense—or, at least, good intentions. Native American, Hispanic, Chinese, and Thai folk medicine all value rattlesnakes or rattlesnake parts for their various purported benefits. Ongoing research should eventually shed light on their various claims. Currently, however, it is clear that those who seek to benefit by eating dried rattlesnake flesh—as do some members of Hispanic communities in larger American cities—face exposure to powerful strains of *Salmonella* bacteria (e.g., *Salmonella arizona*). Closer to the mainstream of Western thought, rattlesnake venom is a matter of considerable biochemical interest—often without fatal results for the snakes involved. In medicine (both Western and nonwestern) and science, the use of snakes is arguably justified by the fact that there is a reasonable expectation that some good will result from a snake's death or removal from the wild. Too often, unfortunately, humans kill snakes gratuitously or, while hiding behind claims of safety, for short-term monetary gain. Studies have shown that even though most motorists swerve to avoid other animals, a disturbingly high percentage encountering snakes attempt to hit them. Humans intent on eliminating a perceived threat or earning some extra money focus on denning sites, where rattlesnakes can be gathered or killed—sometimes in large quantities—during the spring and fall. Entire den sites have also been dynamited or sealed with cement in an attempt to eliminate local populations (99), directly killing numerous snakes in the process and lowering the chances of future survival for others. Roundups encourage both mass killing of rattlesnakes and habitat destruction. When hunters gas suspected rattlesnake holes in an effort to gather animals for these events, they often injure or kill both their intended targets and other inhabitants of these spaces, in the process contaminating the sites and rendering them unfit for future use. Because the gestating females of some rattlesnake species gather in birthing rookeries in summer, they are particularly vulnerable to commercial collection at this time. Rubio observes that such snake hunting is thought to be the single most important factor in the decline of the timber rattlesnake, *Crotalus horridus horridus* (100), although he does not differentiate between collection for the pet or skin trades and collection for the roundups—perhaps because the differences between these varieties of commercial gathering are insufficiently distinct.

Current opinion suggests that rattlesnakes originated in north-central Mexico (9), but certainly they have been successful throughout the Americas. Apparently, they remain capable of successfully dispersing, even across water barriers. An eastern diamondback, *Crotalus adamanteus*, was seen swimming in salt water 22 miles from shore, and others have been seen negotiating the waters of the Florida Keys and Georgia Barrier Islands (128). From an evolutionary standpoint, rattlesnakes have become varied enough that some no longer even possess rattles. One insular form, the Santa Catalina Island rattlesnake, *Crotalus catalinensis*, lacks the structure. Mature specimens of other island species (e.g., the San Lorenzo Island diamondback, *Crotalus ruber lorenzoensis*, and the San Esteban Island blacktail, *Crotalus molossus estebanensis*) have also been found without rattles, which suggests that these insular species could also eventually become rattleless (54). Rattlesnakes embody an impressive degree of diversity and adaption. As Rubio sees it, the main problem with evolution's ongoing experiment with the rattlesnake design is that the human species will cut it short through ignorance, fear, greed, and shortsightedness.

The Boa Manual, by Philippe de Vosjoli, Roger Klingenberg, and Jeff Ronne. 1998. Advanced Vivarium Systems, Inc., Santee, California. 84 pp. and 30 color photos. Softcover. US $8.95. ISBN 1-882770-41-2. (Available from Zoo Book Sales, 403 Parkway Avenue N, P.O. Box 405, Lanesboro, Minnesota 55949-0405, USA).

e-mail: pds0404@aol.com

Currently, there are no fewer than four series of books readily available on the husbandry of various reptiles and amphibians (i.e., AVS, Barron's, TFH, and T-Rex). The quality and utility of these publications varies, and in my opinion the AVS (Advanced Vivarium Systems) series is the best. With the popularity of boas in herpetoculture it is no wonder that the original edition of the red-tailed boa booklet (de Vosjoli 1990) was revised. The new version has been expanded to include color photos and additional text. It is divided into 15 sections including "Responsible Herpetoculture", "Quarantine and the Dark Shadow of IBD", "Maintenance", "Feeding", "Breeding Colombian Boa Constrictors", "The Recognition and Treatment of Diseases and Disorders in Boa Constrictors", and an Index.

In the Introduction, Philippe de Vosjoli explains why co-authors were involved with the revised edition and states the goal of the book: to provide "a thorough introduction to keeping and breeding boas." This is followed by a "General Information" section that lists the subspecies of *Boa constrictor* (as recognized by the authors), and discusses the size, longevity, sexing, and growth of this species.

Next is a one-page, but important section detailing what a person should do before purchasing a boa. Here, the authors point out a few of the mistakes made by many first time buyers: 1) they fail to realize the size attained by large boas; 2) they don't consider the large enclosures needed for adults; and 3) they don't understand that someday their snake may be eating animals such as large rab-

bits. In addition, the authors go on to discuss what is involved in the decision to purchase a large snake such as a boa.

One of the most important parts of this book is titled "Responsible Herpetoculture." Considering the number of news reports about escaped reptiles (including large constrictors) in the U.S. each year, the inclusion of this information seems prudent. Essentially it is a list of recommendations proposed by the American Federation of Herpetoculturists for the keeping and handling of large constrictors. Included are suggestions such as: 1) not displaying these animals in public settings unless in an appropriate forum (e.g., pet stores, herpetological exhibits); 2) transporting them in a secure manner; 3) utilizing secure caging designs; 4) handling them only when an assistant is present; and 5) not allowing minors to keep these animals. There is also an interesting discussion about the increase in the number of agencies proposing legislation that governs the keeping of large constrictors.

Under the heading "Quarantine and the Dark Shadow of IBD," the authors provide a brief discussion of Inclusion Body Disease, a devastating disease that mainly afflicts boas and pythons. They go on to discuss some general rules of proper quarantine that are applicable to the husbandry of all reptiles, not just boas.

For novices, the section titled "Selecting Boa Constrictors" will be particularly useful as it covers the advantages to selecting a captive-bred animal versus one that is wild caught. Also, there is a step-by-step procedure for evaluating the health of a boa being considered for purchase. At the end of this section there is information on keeping groups of boas for breeding and on proper handling.

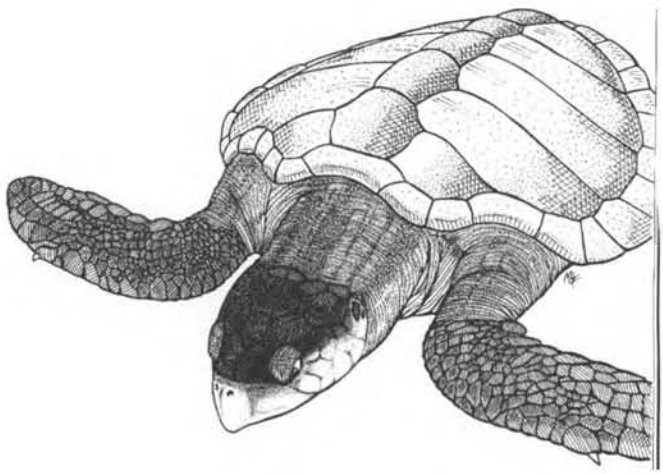
"Housing Boa Constrictors," "Heating and Lighting," and "Feeding" are the next sections, and they really provide the bulk of information needed to properly care for these snakes in captivity. Topics covered include enclosures (types, size, design, landscaping), substrates, shelters, temperature, heating elements, proper lighting, prey size, feeding schedules, feeding problems, and supplying water. Here, readers will find a wealth of practical information that may not be available in more generalized books about reptile husbandry. Following the above information are short sections titled "Shedding" and "Maintenance"; in the latter there are some general guidelines for routine cleaning which will benefit novices.

While many people will most likely be content with maintaining a single boa, seasoned herpetoculturists will find the eight-page section titled "Breeding Colombian Boa Constrictors" (written by Jeff Ronne) of interest. It starts out with a discussion of maturation in boas, and then proceeds to cover topics such as care of breeding boas, cycling, courtship, preovulation swelling, copulation, and ovulation (the information provided is detailed and very useful). The last three pages are concerned with parturition, and include observations about female behavior during and after birth, infertile ova, and the feeding of neonates.

The final section of this book is "The Recognition and Treatment of Diseases and Disorders in Boa Constrictors" (written by Roger Klingenberg, DVM). Included is a detailed discussion of IBD (seven pages) which provides the reader with a solid understanding of this disease. Other ailments discussed include respiratory infections, gastrointestinal disorders, constipation, parasitism, and salmonellosis. Concluding this section are three tables containing additional information about IBD, and a five-page troubleshooting chart for boa health. Undoubtedly, the health chart will be of great value to most herpetoculturists.

Overall, this care book is well done and quite useful. The text is well written and informative, the typeface is clean, and the binding and cover are of decent quality. Furthermore, the inclusion of 41 black-and-white photos and the addition of 30 color photos (not found in the first edition) greatly improve its overall appeal. While a couple of the pictures are of rather poor quality, most range from good to very good. Other assets of this book are the sections on "Responsible Herpetoculture" and "Selecting Boa Constrictors," both of which are topics overlooked all too often by reptile enthusiasts.

One small problem with this book is the location of a two-page section titled "Quarantine and the Dark Shadow of IBD." It would have made more sense to incorporate it into Dr. Klingenberg's section covering diseases and disorders.



The text is relatively free of typos, though I did find a couple (e.g., "asses" for "assess"; p. 30). A couple of incorrectly worded sentences also appear (e.g., on p. 32 it is suggested that you feed one prey item to your snake and then offer it a second. It then goes on to say that if the snake is still hungry you can feed it a second prey item; on p. 60 a sentence reads "During the gestation period the gravid female will typically move toward the warm end of the cage every and spend the night sitting…").

Other problems with this book (some of which are minor) are as follows: 1) the inconsistent presentation of state names (on p. 20 "Kansas" is spelled out but California is abbreviated CA); 2) the "Reference Sources" list at the end of the book is only for Dr. Klingenberg's section on diseases and disorders. It would have been helpful, especially for novices, to have a reference list that applied to the entire book; 3) on p. 22 under the heading "Substrates" there is the subheading "Newspaper and other kinds of paper", though wood shavings, potting soil, and leaf litter are also discussed; and 4) in the Introduction, de Vosjoli says he was impressed by a piece Jeff Ronne wrote for *Reptiles* magazine, but there is no citation for that reference.

Criticisms aside, I encourage novices and boa enthusiasts alike to purchase *The Boa Manual*. Undoubtedly, the amount of information they glean from the pages will vary, but they will easily get their money's worth. The authors have succeeded in fulfilling their goal of providing "a thorough introduction to keeping and breeding boas."

The Origin and Evolution of Larval Forms, edited by Brian K. Hall and Marvalee H. Wake. 1998. Academic Press Inc., 525 B Street, Suite 1900, San Diego, California 92101-4495, USA. xiv + 425 pp. Hardcover. US $79.95. ISBN 0-12-730935-7.

RICHARD WASSERSUG
Department of Anatomy and Neurobiology, Dalhousie University
Sir Charles Tupper Medical Building
Halifax, Nova Scotia, B3H 4H7, Canada
e-mail: tadpole@is.dal.ca

The eleven chapters that make up this book, not counting the editors' Introduction and Epilogue, are packaged under three headings: 1) Larval Types and Larval Evolution, 2) Mechanisms of Larval Development and Evolution, and 3) Larval Functional Morphology, Physiology and Ecology. That's a lot of territory to cover in a single volume.

Not surprisingly, the coverage is uneven and sufficiently spotty that no major syntheses or conceptual breakthroughs come out of this volume. One gets the feeling from the editors' own contributions that even they would accept that criticism. Indeed, one notes that Hall and Wake end their book with an Epilogue titled "Prospects for Research..." rather than a section titled "Conclusions."

The origin and evolution of larval forms is just too broad a topic to ever be covered adequately by a handful of authors, in a dozen or so disparate chapters. The fact is that any all-encompassing advances in our understanding of the origin and evolution of larval forms will ultimately have to deal with the origin and evolution of most metazoan life, for most Metazoa (think insects) have some sort of larval stage. Yet the basic biology of larvae—particularly those of marine fishes and invertebrates—is still too poorly known to yield firm conclusions on their evolution, either in terms of history or mechanisms.

However, such a clip critique of the book as a whole does not do justice to the many superb chapters in *Larval Forms*. Thus, although I do not recommend that anyone attempt to plow through this book cover to cover, some chapters here do deserve broad readership. The four chapters that deal explicitly with vertebrates—my focus in this review—fill over half the pages and are, in my mind, among the best in the book.

If one needs a single article for students to read during that solitary week or so typically devoted to fish larvae in one's single semester ichthyology course, Jackie Webb's 49-page chapter, "Larvae in Fish Development and Evolution," would do the job nicely. It is one of the most readable chapters in the book. Webb doesn't attempt to solve any major controversies in fish evolution, but admirably introduces the diversity of strange adaptations found in fish larvae.

The 47-page chapter "Larvae in Amphibian Development and Evolution" by Jim Hanken does not reach any grand or surprising conclusions either. Hanken focuses strongly on his own work, in areas such as the cranial development of tadpoles. Along the way though he manages to cite a wealth of literature on amphibian developmental biology, much of it within the historical framework that has become something of a trademark in his writing.

Chris Rose does a stellar job in his 49-page review of "Hormonal Control in Larval Development and Evolution—Amphibians," demonstrating an impressive knowledge of endocrinology, amphibian morphology, systematics, and developmental biology. Any researcher studying amphibian metamorphosis who feels insecure in one or more of these areas, would profit from reading Rose's chapter. Despite many excellent chapters on amphibian metamorphosis in the Gilbert et al. (1996) book and the recent (1997) *American Zoologist* symposium devoted to this topic, I have not seen anything as comprehensive as Rose's chapter in *Larval Forms*.

Rose particularly enriches our understanding of salamander metamorphosis, consistently and appropriately formulated in a phylogenetic context. After reading his chapter even I, as an anuran aficionado, had to acknowledge that metamorphosis in urodeles was neither as minor nor monotonous as I had previously supposed. [My one criticism of this chapter is that Rose does not discuss the possible role of peptide growth factors in the control of amphibian larval development.]

The last chapter on vertebrates is Laurie Sanderson and Sarah Kupferberg's 76-page contribution, "Development and Evolution of Aquatic Larval Feeding Mechanisms." Despite its title, this chapter only mentions invertebrates in passing and really deals with fish and amphibians. However, like Rose's, this chapter is otherwise outstandingly comprehensive. Sanderson is, by training, a fish ecomorphologist and Kupferberg an amphibian ecologist. Together they demonstrate a wonderful ability to assimilate and summarize an enormous amount of literature in areas far beyond their own core research. Hopefully they will continue to collaborate. I could find only a few things to quibble about in this chapter and they were all minor. For example, there is a statement that "flaps on the nares serve as external valves," when tadpoles pump water through their mouths. This may mislead some readers, who don't know tadpole morphology, into thinking that those narial valves are external, whereas in most tadpoles narial valves are internal. Much of the anuran larval biology covered in this chapter will undoubtedly also be covered in the new McDiarmid and Altig (1999) *Tadpole* book. Nevertheless I would be surprised if the literature summary there, on tadpole feeding, is more exhaustive than Sanderson and Kupferberg's.

In general, the literature reviewed within this book is a major strength and makes the volume a valuable resource, despite any criticism that I or others might raise overall. A bit more than a quarter of the pages from the chapters mentioned above are reference lists. Collectively those four chapters cite over a thousand papers!

This, however, does not mean that the information in this book is easily absorbed. Unfortunately most of the chapters, including those listed above (Webb's is an exception) assume that the readers are knowledgeable in anatomy, systematics, or both. Whereas much of the book is devoted to the embryonic origins of larvae or their metamorphic transformation, not much space is given to introducing or illustrating larval forms *per se*. Thus the undergraduate, who has not had some morphology and taxonomy courses, will probably find the book overwhelming. The invertebrate zoologist, who has not worked with fishes and amphibians, would similarly have a hard time grasping all the information in the chapters mentioned above.

Another caveat: the word "heterochrony" gets used by most of the authors in this book, but if one is not sure whether heterochrony is a powerful explanatory concept in evolutionary biology or just overused jargon, this book will not help them decide. The problem is that the term is used in slightly different contexts by the various authors. Mike Hart and Greg Wary, in a brief chapter (7 pp.), succinctly titled "Heterochrony," are down on the term, arguing that it is of limited value in the discussion of larval origins at the highest levels. Evidently, though, few if any of the other contributors to this book read the Hart and Wary chapter before signing off on their own submissions. If one takes the time to struggle with the subtleties of definitions, one can reconcile the different uses of "heterochrony" in the different chapters. However, on a first pass, the average reader may feel more confused than enlightened about the term.

In their Epilogue, the editors reiterate areas for additional work—an appropriate action in the absence of any big breakthroughs in our understanding of larval evolution. There, Hall and Wake make the following statement (p. 412): "An 'ancient and honorable' question that is not fully answered, nor even fully grasped, is why larvae evolved at all. The facile answer usually provided is that larvae contribute to the survivorship of species by diversifying both the larval and adult life forms and thereby the habitat and resources available." I believe that this so-called "facile answer" is a bit of a strawman, and a dated one at that. This answer has certainly been recognized for some decades *not* to apply to taxa such as many marine invertebrates that have non-feeding larvae which are simply a dispersal stage for otherwise sessile organisms.

It similarly does not hold for holometabolous insects or anurans, that have obligate metamorphosis. From an ecoevolutionary perspective, the larval stage of these taxa evolved to allow these organisms access to patchy resources, limited in time and space. This view, I believe, is accepted by most ecologists who work with these organisms.

That is not to say that the question of "Why have larvae evolved?" is fully answered. It is not. But it is as absurd to expect one true answer to this question as it is to expect the topic of the origin and evolution of larval forms to be adequately covered in a single multi-authored volume.

PUBLICATIONS RECEIVED

Of Frogs and Toads, Poems and Short Prose Featuring Amphibians, edited by Jill Carpenter. 1998. Ione Press, P.O. Box 3271, Sewanee, Tennessee 37375, USA. xii + 131 pp. Softcover. US$ 10.95 ($3.50 shipping for first copy, $1.00 each additional). ISBN 0-9666674-0-9.

This volume contains 88 contemporary poems and (very) short stories relating to amphibians. The majority of these focus on anurans, but urodeles are also treated in a number of works (no caecilians, however). Although some contributions are purely fanciful, others touch on a variety of aspects of amphibian biology, including reproduction, vocalization, and metamorphosis. Many of the poems make reference to the phenomenon of disappearing amphibians. The literary works are supplemented by ten line drawings.

The Gigantic Land Tortoises of the Galapagos Archipelago, by John Van Denburgh. 1998. Society for the Study of Amphibians and Reptiles, Ithaca, New York. xiii + 172 pp., 101 pls. Hardcover. US $55.00 ($3.00 shipping). ISBN 0-916984-46-X.

This is a facsimile reprint of the classic work by Van Denburgh on Galapagos tortoises based on the extensive material collected by the California Academy of Sciences expedition to the islands during 1905–1906. The original work contained detailed measurements for all of the 266 specimens collected on an island by island basis. Representatives of each of the forms recognized by Van Denburgh are represented in dorsal, lateral, and frontal view in the black and white photographs that constitute the majority of the 101 plates. The text includes a historical overview of early accounts of giant tortoises, as well as an extensive systematic account of the animals. This facsimile edition is accompanied by a nine-page foreword by Peter C.H. Pritchard that places the Academy expedition in its historical context and highlights the importance of Van Denburgh's monograph. Also provided are a map of the expedition's route through the archipelago, several historical photos, and a table comparing Van Denburgh's taxonomy to that employed by several more recent workers.

Frogs, A Wildlife Handbook, by Kim Long. 1999. Johnson Books, 1880 South 57th Court, Boulder, Colorado 80301, USA (e-mail: books@jpcolorado.com). Softcover. US $15.95. ISBN 1-55566-226-9.

This is an idiosyncratic guide to anurans of North America, their biology, and their place in human culture. Each species account includes an illustration (most in color), range map (with some inaccuracies), brief description, and comments on vocalization. Oddly, the author has segregated all species with the word "toad" in their common names. These do not have color illustrations and are not provided with full species accounts. Short sections on reproduction, larval life, anatomy, and other basic frog biology are also presented. Much of the remainder of the book deals with frogs in mythology, folklore and Native American tradition. A section on frog names provides foreign language terms for frogs as well as derivations of the specific names of most North American taxa. Although this is an interesting feature not present in competing titles, readers should be aware that there are errors (for example, collectors and describers are not differentiated, resulting in some misleading statements). The book concludes with a short bibliography and list of other sources and is indexed by common name and subject.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986–1998, *et. seq.* Privately published by and available from the author (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024, USA). Individual accounts available separately. Cost: US $0.10/page + postage and handling.

The most recent installments (numbers 18–20) in this series are the three species of *Holbrookia* occurring in Texas: *H. maculata* (Lesser Earless Lizard), *H. propinqua* (Keeled Earless Lizard), and *H. lacerata* (Spot-tailed Earless Lizard). These new accounts comprise 44 pages in addition to a detailed range map. Axtell provides an in-depth discussion of distribution for each species in Texas, along with current taxonomy, geographic variation, conservation status, and suggestions for future work. Among the taxonomic changes proposed are the elevation to species status of *H. m. approximans* and *H. m. elegans*.

Les serpents venimeux du monde:
systématique et répartition
(Venomous Snakes of the World: Systematics and Distribution)

Patrick David & Ivan Ineich

Preface by Hubert Saint-Girons

Dumerilia: volume 3

A herpetological journal published at the Paris Natural History Museum.

This work is bilingual (French/English). Species accounts include: valid scientific name; primary reference (original name of the taxon, describer(s), year of description and bibliographical data); type-locality; currently recognized subspecies, if any, with their author(s) and year of description; common French and English names; references; distribution by country, with references; comments.

In the second part, all venomous snake species are listed by country. An annotated bibliography of more than 1,700 references and three indices conclude this new major reference work essential for all herpetologists, physicians and members of the health services interested in venomous snakes. - Published in March 1999, 499 pages.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700		$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$270

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1999 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

2000 — Universidad Autónoma de Baja California Sur, La Paz, BCS, México, 14–20 June 2000 (Carlos Villavicencio, Chair).
2001 — Indiana University/Purdue University, Indianopolis, Indiana, USA, 26–30 July 2001

About Our Cover: *Anolis transversalis*

Anolines comprise a large group of lizards within the Polychrotidae, with more than 300 known species (Lee 1996. The Amphibians and Reptiles of the Yucatán Peninsula. Comstock Publishing Associates. Ithaca, New York. 500 pp.). Collectively, they range from the southeastern United States, through México, Central America, and the Antilles to approximately 20° S in South America. Although primarily arboreal, there are semiarboreal, terrestrial, and even semiaquatic species known.

Anolis transversalis, described by Duméril in 1851, occurs in western Amazonia in Colombia, Ecuador, and Peru, and in the Brazilian states of Acre, Amazonas, and Rondônia (Avila-Pires 1995. Lizards of Brazilian Amazonia [Reptilia: Squamata]. Zoologische Verhandelingen. [299]:1–706). It is readily distinguished from all other anoles found within its range by the combination of smooth head scales and a distinctive color pattern of transverse markings on the body (Duellman 1978. The Biology of an Equatorial Herpetofauna in Amazonian Ecuador, Univ. Kansas Misc. Publ. No. 65, 352 pp.). Adult color pattern is sexually dimorphic, with females prominently banded; the dorsum of males tends toward black speckling rather than banding. Owing to differences in coloration, males were described in 1880 by O'Shaughnessy (1880. Proc. Zool. Soc. London 1880:491–493) as another species, *A. buckleyi*, which was demonstrated by Williams and Vanzolini (1966. Papeis Avulsos 19:197–204) to be conspecific with *A. transversalis*.

Adults of both sexes possess a well-developed dewlap and beautiful cerulean eyes. Female dewlap coloration is chocolate brown with the enlarged scale rows and the ventral edge yellowish tan. Male dewlap colors vary from lemon-orange to reddish-orange with the enlarged lateral scale rows varying from light green to yellowish (Dixon and Soini 1986. The Reptiles of the Upper Amazon Basin, Iquitos Region, Peru. Milwaukee Public Museum. 154 pp). Males are 79–83 mm SVL, females 69–81 mm SVL.

Although most frequently seen descending trunks of large trees in closed canopy forest, specimens have been collected on leaves and small branches as low as 1.5 m. The species is thought to occupy mainly the upper levels of the forest, in or near the canopy of large trees (Dixon and Soini, *op. cit.*; Duellman, *op. cit.*).

The adult female depicted on the cover was photographed by **David T. Roberts** at the Madre Selva II Biological Station located on the Río Orosa, Loreto, Peru. The Río Orosa is a small tributary on the south bank of the Amazon River approximately 125 km east of the city of Iquitos. The photograph was taken with a tripod-mounted Canon F1 camera and a Vivitar 100mm macro lens. The natural light exposure was made during the early afternoon on Fujichrome Velvia film, at an aperture setting of f11 and a shutter speed of 8 seconds. David is a research technician at the Dallas Zoo's Department of Herpetology. He has spent the past 15 years photographing a variety of life forms in North, Central, and South America. His favorite photographic subjects include reptiles, amphibians, insects, and arachnids. David frequently teaches rainforest photography workshops at the Madre Selva II Biological Station for Nature's Images, Inc. His photographs have appeared in a variety of scientific and popular publications.

Separation and imaging of Roberts' photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

Kennedy Student Award Committee Annual Report—1999

The Kennedy Award Committee has completed its work for Volume 32 of the *Journal of Herpetology*. The Committee has selected "Predator mediated patch use by tadpoles (*Hyla regilla*): risk balancing or consequences of motionlessness?" by Sarah J. Kupferberg (Vol. 32:84–92). The Kennedy Award carries with it a cash prize of US $200 or the winner's selection of any SSAR publications valued at twice that amount.

Nine manuscripts were in competition this year. The Committee noted the high quality of the submitted papers. Committee members were: Robin Andrews (Virginia Polytechnic Institute & State University), David Duvall (Oklahoma State University), Mary Mendonça (Auburn University), Terry D. Schwaner (Southern Utah University), and Robert E. Gatten, Jr., Chair (University of North Carolina).

SSAR Board Appoints New Secretary

John Matter has been appointed SSAR Secretary, replacing Ellen Censky, who has resigned owing to the press of duties associated with her recent appointment as Director of the Connecticut Museum of Natural History. SSAR extends its gratitude to Ellen for her service to the Society. As of September 1, 1999, all matters pertaining to the Secretary's office should be directed to: *Dr. John M. Matter, Biology Department, Juniata College, Huntington, Pennsylvania 16652, USA; e-mail: matter@juniata.edu.*

Membership Options for the Society for the Study of Amphibians and Reptiles Effective for the Year 2000

Life membership is now available for the Society for the Study of Amphibians and Reptiles. You can make a single payment of US $1250 or four equal annual payments of US $325. Look for the renewal envelope in the September issue of *Herpetological Review*. You may renew your regular individual membership for up to three years or your student membership for two years at the current rate. You can also renew via e-mail with your VISA/MasterCard at *ssar@slu.edu*.

Managing Editor Sought for *HR*

Herpetological Review is seeking to fill the position of Managing Editor, to replace Tom Tyning, who would like to step down in the not-too-distant future. Among other qualifications, the Managing Editor should be skilled in the use of page composition software, such as PageMaker. Inquiries may be directed to the Editor, Robert Hansen, by e-mail at *rwh13@csufresno.edu*.

HR Staff Changes

Brad Hollingsworth (San Diego Natural History Museum) and Gunther Köhler (Forschungsinstitut und Naturmuseum Senckenberg) have joined the *Herpetological Review* staff as Associate Editors. Dan Beck, Associate Editor, has resigned following several years of outstanding service to the herpetological community. On behalf of SSAR, the editors thank Dan for his efforts.

SSAR Web Site Moved

After many years at http://falcon.cc.ukans.edu/~gpisani/SSAR.html we recently have moved the SSAR web site to

http://www.ukans.edu/~ssar/.

The old site will forward users for sometime to come, but links and bookmarks should be updated to reflect the change. The mirror site at http://www.ukans.edu/cwis/units/biol/SSAR/SSAR.html will remain operational.

NEWSNOTES

Graduate and Post-Graduate Research Grants

The Biological Research Station of the Edmund Niles Huyck Preserve offers grants (max. = $2500) to support biological research which utilizes the resources of the Preserve. Among the research areas supported are basic and applied ecology, animal behavior, systematics, evolution, and conservation. The 2000-acre Preserve is located on the Helderberg Plateau, 30 miles southwest of Albany, New York. Habitats include northeast hardwood-hemlock forests, conifer plantations, old fields, permanent and intermittent streams, 10 and 100-acre lakes, and several waterfalls. Facilities include a wet and dry lab, library, and houses/cabins for researchers. Deadline = 1 February 2000. Application material: *Dr. Richard L. Wyman, Executive Director, E.N. Huyck Preserve and Biological Research Station, P.O. Box 189, Rensselaerville, New York 12147, USA.*

MEETINGS

Meetings Calendar

2–4 October 1999—Australian Herpetological Society, 50th Anniversary Conference on Captive Husbandry and Conservation of Reptiles, Sydney, Australia. Contact: Daniel Holloway (e-mail: ozherps@zip.com.au) or visit the Society's web page (www.ozherps.zipworld.com.au).

5–9 October 1999—The Sixth Annual Conference of the Association of Reptilian and Amphibian Veterninarians, Columbus, Ohio, USA. For conference registration information contact: Wilbur Amand, VMD, PO Box 605, Chester Heights, Pennsylvania 19017, USA; fax: 610-892-4813.

8–11 October 1999—Second Symposium on the Status and Conservation of Florida Turtles, Eckerd College, St. Petersburg, Florida, USA. Contact: Gopher Tortoise Council, c/o George L. Heinrich, 1223 Alhambra Way S., St. Petersburg, Florida 33705-4620, USA; tel. (813) 865-6255; e-mail: highpine@gte.net.

15–18 October 1999—Canadian Amphibian and Reptile Conservation Network/Rèseau Canadien de Conservation des Amphibiens et des Reptiles Annual Meeting, Quèbec City, Quèbec, Canada. Contact: Stan A. Orchard, Chairman, CARCNet, 1745 Bank Street, Victoria, British Columbia, Canada V8R 4V7; Tel/Fax: 250-595-7556; e-mail: sorchard@islandnet.com.

25–28 October 1999—The 5th Biennial Conference on Research on the Colorado Plateau, Flagstaff, Arizona, USA. For more information see the conference web site (www.usgs.nau.edu/conference).

12–17 December 1999—5th Latin American Congress of Herpetology, University of Uruguay, Montivideo, Uruguay. Abstract deadline 30 June 1999. For registration and information contact: Lic. José A. Langone, Secretario Ejecutivo V CLAH, Museo Nacional de Historia Natural, CC 399, 11000 Montivideo, Uruguay (e-mail: vclah@fcien.edu.uy). Within the U.S. or Canada, contact: Dr. Rafael de Sá, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA (e-mail: rdesa@richmond.edu). Web site: http://zvert.fcien.edu.uy/clh.

1 April 2000—All Florida Herpetology Conference, Florida Museum of Natural History, Gainesville, Florida. For more information, contact Max Nickerson, Florida Museum of Natural History, University of Florida, Gainesville, Florida, 32611 USA (email: maxn@flmnh.ufl.edu).

LEGISLATION & CONSERVATION

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles and their habitats. Please direct all communications to the section editor, Jeffery Demuth (postal and e-mail addresses on inside front cover).

USA: Louisiana: Act 81 of the 1999 Session of the Louisiana Legislature prohibits the commercial harvest of Louisiana's native box turtle (*Terrapene* spp.) populations. The law was unanimously passed by both the Louisiana Senate and House of Representatives and goes into effect August 15, 1999. This victory for one of Louisiana's turtles also will impact box turtles in other states.

Any box turtles native to the state of Louisiana will be considered as originating from Louisiana. Therefore, it will no longer be possible to smuggle box turtles out of other states, where harvest is also illegal, and claim they originated in Louisiana. Additionally, recreational possession is limited to four box turtles.

Since January of 1995, approximately 29,896 box turtles were collected for the pet trade and shipped from Louisiana. This law will help to ensure the future of box turtles in Louisiana and throughout their range.

For more information contact: *Martha Ann Messinger, 2022 Gemini Drive, Bastrop, Louisiana USA 71220-3467, Tel.: (318) 281-0113, e-mail: gpatton@bayou.com.*

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Anne Maglia or Christopher Sheil; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.herplit.com/contents

Interactions Between Mole Salamanders and Sirens

The author utilized field sampling and experiments in artificial and natural ponds to study the interactions between two top amphibian predators (branchiate adult *Ambystoma talpoideum* and *Siren intermedia*) of temporary ponds in southeastern United States. The author found the abundance and distribution of these species to be independent; however, *A. talpoideum* was more abundant and widespread than *S. intermedia*. Within a particular pond, captures of these two species were negatively correlated, and results of this research suggest that paedomorphic *A. talpoideum* avoid those traps containing *S. intermedia*—experiments in artificial ponds supports this asymmetrical interaction. Interestingly, experiments in artificial ponds also indicated that *S. intermedia* reduced both recruitment and growth of *A. talpoideum* and did not experience reciprocal negative or positive effects. These results suggest that *S. intermedia* competes with, and is an intraguild predator of, *A. talpoideum*.

FAUTH, J. E. 1999. Interactions between branchiate mole salamanders (*Ambystoma talpoideum*) and lesser sirens (*Siren intermedia*): asymmetrical competition and intraguild predation. Amphibia-Reptilia 20:119–132.

Amphibians and Reptiles Introduced into Colorado

The authors summarize records (University of Colorado specimens, literature review [including newspapers], contacting field biologists, and conducting field surveys of sites) of amphibians and reptiles introduced into Colorado, providing a list of those species introduced and the modes by which they likely were released, and they discuss which species have subsequently established populations. Information included by the authors can be used in the development of policies concerning importation, translocation, and release of captive specimens.

LIVO, L. J., G. A. HAMMERSON, AND H. M. SMITH. 1998. Summary of amphibians and reptiles introduced into Colorado. Northwestern Naturalist 79:1–11.

Reproduction in the Suwannee Cooter

From 1988 to 1993, the authors studied the reproductive biology of *Pseudemys concinna suwanniensis*, the largest North American emydid, in the headwaters of the Wakulla River in northern Florida. At the study site, various aspects of the reproductive biology of these turtles were determined. Based on these data, the authors found size at sexual maturity to be more a function of size than of age and females were found to lay as many as five or more clutches at 16–25 day intervals; most females were found to lay eggs annually. Average annual production of eggs was approximately 70 eggs per female; clutch mass was found to increase with body size, but relative clutch mass did not. Data from hatchlings also were collected, and hatchlings were found either to exit nests in fall or to overwinter and leave the nest in early spring. Temperature-dependent sex determination is the means of sex determination in *P. concinna suwanniensis*, and the primary predators of eggs at this site were raccoon (*Procyon lotor*) and fish crows (*Corvus ossifragus*). The authors present management recommendations for this and other species of turtles in Florida.

JACKSON, D. R., AND R. N. WALKER. 1997. Reproduction in the Suwannee Cooter, *Pseudemys concinna suwanniensis*. Bulletin of the Florida Museum of Natural History 41(2):69–167.

Distribution of Northern Redback Salamanders

The authors examined the effects of selective logging (a process that leaves gaps in the forest canopy) on the distributions of individual *Plethodon cinereus* in a patch of forest that had been selectively logged one year earlier. Leaf litter searches and inspection under cover objects were made to assess salamander densities and distributions. Comparisons were made between quadrats inside gaps, along the edges of gaps, and within the forest. Though variation in salamander numbers was found among transects, no significant differences were found in the densities of salamanders among the three quadrat catagories. The result of this investigation suggest that newly formed tree gaps did not strongly affect the distributions of *P. cinereus* in the first year following selective harvest of trees.

MESSERE, M., AND P. K. DUCEY. 1998. Forest floor distribution of northern redback salamanders, *Plethodon cinereus*, in relation to canopy gaps: first year following selective logging. Forest Ecology and Management 107(1998):319–324.

Molecular Phylogeny of Endangered Madagascan Tortoises

Employing mitochondrial DNA sequences for the 12S and 16S rDNA and cyt *b* genes, the authors address the controversial issue of the phylogenetic relationships among the four endemic and

endangered tortoises (*Pyxis arachnoides, P. planicauda, Geochelone radiata,* and *G. yniphora*) of Madagascar; a fifth species is not endangered and is not endemic to Madagascar. For their analysis, outgroup taxa were selected from mainland Africa (*G. pardalis*), Galápagos (*G. nigra*), and North America (*Gopherus polyphemus*). The results of their analysis indicate that both species of *Pyxis* are sister taxa and that *Pyxis* is grouped within *Geochelone*. Also, the authors propose that the two species of Madagascan *Geochelone* are sister taxa, and that the endemic Madagascan taxa form a monophyletic group as the result of a single colonization event. The authors suggest founding by rafting as the means of colonizing the island some time after the separation of Madagascar from other land masses (90–165 mya).

Predation on Lizard Eggs by Ants

One explanation for long-term fluctuations in population density of a species is that the intensity of interactions between species in a community is variable. The authors state that the population may experience variation in the intensity of species interactions if density of a species with which the population directly interacts changes, and/or if the strength of the interaction changes. Previous work on *Anolis limifrons* at Barro Colorado Island, Panama indicated that the density of this lizard is negatively correlated with the amount of wet-season rainfall, that fluctuations in density are related more to variation in egg mortality than to variation in lizard mortality or fecundity, and that most egg mortality is the result of predation by ants (*Solenopsis*). By manipulating litter moisture at experimental plots to simulate wettest and driest wet seasons over the last two decades, as well as monitoring the density of *Solenopsis*, amount of egg mortality, and rate of predation, the authors tested these previous hypotheses. Results of these experiments indicate that egg mortality was greater in the wettest, rather than driest, treatments, and that all egg mortality was the result of predation from *Solenopsis*. Also, as indicated by ANCOVA, the amount of egg mortality was higher on plots with greater densities of ants; however, treatment effects explained more variation than did *Solenopsis* density, and water manipulations did not change the density of *Solenopsis*. These results support the hypothesis that annual variation in the amount of wet-season precipitation indirectly produces parallel variation in annual density of *A. limifrons* populations by modifying the rate of ant predation on eggs.

Evidence for the Monophyly of Australian Gekkonoid Lizards

Mitochondrial 12S rRNA and nuclear c-*mos* genes were partially sequenced for twelve members of the four major lineages of geckos of the Australian region (Pygopodidae, Gekkoninae, and Diplodactylini, and Carphodactylini [Carphodactylinae]) and an outgroup in the Eublepharinae. Sequences from both genes were combined into a single data matrix and both maximum likelihood and parsimony algorithms were employed to generate phylogenetic hypotheses for the thirteen taxa. The molecular-based hypotheses of relationships were used to comment on the debate over relationships among these groups, the monophyly of the diplodactyline tribes, and the conflicting hypotheses of relationships of the pygopods and the genus *Oedura*. The results of these analyses support the monophyly of the Diplodactylini, with *Oedura* as a member of this tribe. The Carphodactylini was found to be a paraphyletic group, with the four genera positioned at the base of the Diplodactylini. Pygopods were found to be well nested within the Gekkonidae, with pygopods and diplodactylines forming a well-supported monophyletic group.

Costs of Exploiting Poisonous Prey

The authors discuss and present evidence of an evolutionary trade-off in a predator-prey interaction in which a species of garter snake (*Thamnophis sirtalis*) has evolved resistance to the extreme neurotoxin (tetrodotoxin) of its prey (*Taricha granulosa*). Within a population of *T. sirtalis*, resistance to tetrodotoxin varies among individuals, and this variability has a genetic basis. Among populations, the levels of newt toxicity and snake resistance, though somewhat variable, roughly match. The authors suggest that this represents a geographic mosaic of coevolutionary outcomes in this predator-prey interaction. Employing bioassays to detect individual differences in suceptibility to tetrodotoxin, the authors investigated whether resistance and locomotor performance were negatively associated (i.e., whether they represent a trade-off between predatory and antipredatory abilities of *T. sirtalis*). Patterns of among-family variation in this system suggests a genetic basis of the trade-off exists, and the regression of postinjection speed on baseline speed indicates the existence of a trade-off in resistant and nonresistant populations of *T. sirtalis*.

International Conservation: Sustainable Use of Crocodilians

Thorbjarnarson reviews the history of the exploitation of crocodilians for their skins over the past century and the effects of that exploitation on the conservation status of species involved in international trade. Of particular concern are the boom-and-bust cycles of these markets, as well as fears of lack of market elasticity that demonstrate the vulnerability of conservation programs based on the sale of wildlife products for luxury markets. Thorbjarnarson presents the history of the international trade of products from crocodilians as an insight into the value (and perhaps more importantly the limits) of a sustainable-use approach to conservation.

THORBJARNARSON, T. 1999. Crocodile tears and skins: international trade, economic constraints, and limits to the sustainable use of crocodilians. Conservation Biology 13(3):465–470.

INSTITUTIONS

Herpetological Collections in New Zealand Museums

B. J. GILL
Auckland Museum, Private Bag 92018
Auckland, New Zealand

and

RAYMOND COORY
Museum of New Zealand, P.O. Box 467
Wellington, New Zealand

New Zealand's major museums were founded in the Victorian era in the second and third decades after New Zealand became a British Colony in 1840. Four main museums developed, one in each of the country's four main towns. Distributed across the country from north to south, they are: Auckland Museum, Auckland (AIM), Museum of New Zealand, Wellington (NMNZ), Canterbury Museum, Christchurch (CMC) and Otago Museum, Dunedin (OM). (Institutional acronyms follow Leviton et al. [1985].)

In the very early years, with few staff and small budgets, locally-obtained natural history material was readily available, but there was a problem in having specimens expertly prepared, and in properly storing and displaying them. It was a time when much material continued to be sent directly to northern hemisphere experts and institutions, particularly in Britain, for identification or description. As a result, New Zealand museums tend to have little local natural history material from before 1880, and those specimens that survive from this era tend to be documented poorly.

TABLE 1. Taxonomic spread of herpetological specimens in New Zealand museums. Refer to text for explanations of museum acronyms.

	AIM	NMNZ	CMC	OM	Total
Anura	185	512	119	42	858
Other Amphibia	20	7	1	10	38
TOTAL AMPHIBIA	205	519	120	52	896
Testudines	45	56	19	33	153
Crocodilia	20	15	11	7	53
Sphenodontida	80	272	222	46	620
Squamata	1592	5005	283	376	7256
Other Reptilia	80	93	85	0	258
TOTAL REPTILIA	1817	5441	620	462	8340
Grand Total	2022	5960	740	514	9236

Since 1900 the museums have striven to develop and maintain comprehensive collections of local natural history both for research and display. All four main museums have valuable reference collections and good natural history displays; the latter either recently refurbished or in process of upgrading. Among the various branches of natural history, herpetology has tended to be a relatively minor activity in New Zealand museums, reflecting the size of the herpetofauna. The New Zealand herpetofauna numbers more than 60 species. In contrast there are nearly 400 species of birds on the New Zealand list, and ornithology has always attracted more attention in museums than herpetology.

There has been little large-scale systematic collecting of amphibians and reptiles for New Zealand museums. The most notable exception is the large collection of New Zealand lizards built up by Tony Whitaker and colleagues for Ecology Division of the Department of Scientific and Industrial Research. After the closure of the latter department these herpetological collections were incorporated with those of NMNZ. Smaller and less well-documented research collections include the skinks collected by Graham Hardy while a student at Victoria University, Wellington, (specimens now at NMNZ), and the lizards collected by J. Robb during her teaching career at Auckland University (specimens now at AIM).

TABLE 2. Geographic spread of collecting localities of herpetological specimens in New Zealand museums.

	AIM	NMNZ	CMC	OM	Total
New Zealand	965	5108	520	286	6879
Pacific Islands	727	330	32	19	1108
Other	330	522	188	209	1249

The four main New Zealand museums have herpetological collections numbering over 9000 specimens. The breakdown of the collections by taxonomic group, geographic source, and mode of preservation is shown in Tables 1–3. The largest collections are at NMNZ and AIM, and further details of herpetology at these institutions follow. Squamates (mainly lizards) are the biggest single taxonomic group reflecting the dominance of lizards in the New Zealand herpetofauna. The 620 tuatara specimens (Sphenodontida) include large numbers of subfossil bones. Three-quarters of the specimens in New Zealand museums are New Zealand species, while 12% are from islands of the Pacific.

Museum of New Zealand, Wellington (NMNZ)

New Zealand's national museum (funded by the government, unlike the others which are funded by local bodies) began in 1865 as the Colonial Museum and Geological Survey, after which it became the Dominion Museum (1907), then National Museum of New Zealand (1973). The present name Museum of New Zealand Te Papa Tongarewa ("Te Papa" for short) was adopted in 1992.

The Museum of New Zealand has the largest and most comprehensive collection of New Zealand amphibians and reptiles, and incorporates the collection of the former Ecology Division (Department of Scientific and Industrial Research). The collection includes 20 holotypes and about 35 other type specimens. The fossils in the collection are Cretaceous marine reptiles from Canterbury and Kaikoura, and include the oldest items in the collection, some having been collected in 1869.

The collection is biased in favor of material from northern North Island and the Wellington and Marlborough areas. The museum has never had a full-time herpetologist, but curators of other vertebrate groups have managed the herpetological collections and pursued herpetological research. Past curators include Charles McCann (1899–1980), who wrote a monograph on New Zealand lizards (McCann 1955), and Graham Hardy, who revised the New Zealand skinks (Hardy 1977). Currently the collection is maintained by a part-time collection manager. An electronic database of the collection is being developed but is not yet complete.

Auckland Museum, Auckland (AIM)

Sometimes referred to as the Auckland War Memorial Museum, and known until recently as the Auckland Institute and Museum, this museum was founded in 1852. The herpetological collection is managed by a curator and part-time technician who deal also with the other land vertebrates, especially birds.

TABLE 3. Mode of preservation of herpetological specimens in New Zealand museums.

	AIM	NMNZ	CMC	OM	Total
Whole in alcohol	1707	5200	227	331	7465
Bones & subfossil bones	110	596	365	79	1150
Fossils (including casts)	140	34	110	0	284
Mounts (including casts & models)	35	10	35	82	162
Other	30	120	3	22	175

Little locally-collected material survives from last century, but large exchanges with northern hemisphere museums in the last 25 years of last century brought in much foreign material that still survives. The oldest herpetological specimen is a skink (*Oligosoma smithi*) in alcohol (H613; paralectotype of *Mocoa smithi* Gray, 1845) collected in the Bay of Islands, New Zealand, in 1841 by the *Erebus* and *Terror* Antarctic Expedition. It was obtained by exchange from the British Museum (Natural History). The oldest New Zealand specimen originally collected by the museum is a sea snake *Pelamis platurus* (H335) that was probably collected c. 1868. No tuatara or lizard specimens survive in the collection from last century. The oldest specimen exchanged last century is a skeleton of *Python sebae* (H644) received from the Paris Natural History Museum in 1878.

The herpetological collection grew slowly and exceeded 1000 specimens only within the past 15 years. The collection records are now computerized. Most New Zealand species are represented in the collection, with a bias towards those of the northern North Island. Specimens from the islands of the southwest Pacific make up 36% of the collection (Table 2).

The collection contains some seven primary type specimens of New Zealand species, and about 28 secondary types. Graham Turbott (1914–) was in charge of land vertebrates at Auckland Museum when he described the third New Zealand native frog *Leioplema archeyi* (Turbott 1942).

Acknowledgments.—We thank Erena Barker (OM) and Geoff Tunicliffe (CMC) for providing statistics for the collections that they manage, and Tony Whitaker for comments on a draft of this report.

Standard Field Codes for North American Amphibians

JOHN E. FAUTH
Department of Biology, College/University of Charleston
66 George Street, Charleston, South Carolina 29424-0001, USA
e-mail: fauthj@cofc.edu

Coordination of amphibian monitoring efforts would be aided by simple, easy to remember field codes for amphibian species. Much as standard common names (Collins 1997; U.S. Department of Agriculture 1999) aid communication, standardized field codes facilitate computerized entry, storage, retrieval, searching, and exchange of data. Other biological disciplines have standard field codes: ornithologists use alphabetical ("alpha") and numerical codes for birds based on their common names (American Ornithologists' Union 1983; U.S. Geological Survey 1999a), while studies of amphibians and reptiles have used alphabetical codes for organisms based on their scientific names (e.g., Corn 1994:116; Scott 1994:82). The North American Amphibian Monitoring Project (U.S. Geological Survey 1999b) has a numerical code (AMP#) for amphibians, but the correspondence between species names and numbers is obscure (how many herpetologists know what species is AMP# 228?), so researchers would have to carry a list of species names and numbers into the field to avoid making mistakes. This defeats one purpose of a code, namely ease of use.

TABLE 1. Field codes for currently recognized North American amphibians and others assigned AMP# (U.S. Geological Survey 1999b, based on U.S. Department of Agriculture 1999) that are exceptions to the standard convention of using the first letter of the genus followed by the first three letters of the specific epithet. Only RCAC and RCAS co-occur. Note that using a longer code (5 or 6 letters) would only separate two-thirds of these problematic cases.

Code	Scientific name (common name)	Original code retained by
AMAR	*Ambystoma macrodactylum* (long-toed salamander)	*A. maculatum* (AMAC)
DAUC	*Desmognathus auriculatus* (southern dusky salamander)	*Dendrobates auratus* (DAUR)
PCAV	*Pseudacris cadaverina* (California treefrog)	*Plethodon caddoensis* (PCAD)
PHUR	*Phaeognathus hubrichti* (Red Hills salamander)	*Plethodon hubrichti* (PHUB)
PSTC	*Pseudacris streckeri* (Strecker's chorus frog)	*Pseudobranchus striatus* (PSTR)
RCAC	*Rhyacotriton cascadae* (Cascade's torrent salamander)	*Rana cascadae* (RCAS)
SINR	*Spea intermontanus* (Great Basin spadefoot)	*Siren intermedia* (SINT)

I use a simple four-letter code in the field and add the AMP# in the data processing stage using "if . . . then . . ." statements in my computer program. The field code is easy to remember: the first letter of the genus is followed by the first three letters of the specific epithet (e.g., *Rana areolata* = RARE). This system provides 26^4 (456,976) unique combinations, with only seven codes shared by different species of North American amphibians (Table 1). For these cases, a unique combination is created using two rules. 1. The species with the shorter specific epithet retains the original code, and the last letter of the other species' code is replaced by the next consonant in its specific epithet. 2. If species in different genera share the same specific epithet, then the species with the shorter genus retains the original code and the other substitutes the next consonant in its epithet (Table 1). Only one pair of species that requires using these rules co-occurs (*Rhyacotriton cascadae* and *Rana cascadae*), reducing the chances of recording the wrong code in the field.

This system has six advantages. 1) It is simpler to remember and use in the field than the AMP#. It should be easy to remember —or to decipher —that *Rana catesbeiana* is RCAT (AMP# 228). This is especially important for beginning herpetologists or volunteers monitoring populations, who often have trouble remembering obscure codes. Basing the field code on scientific names instead of common names reinforces the importance of systematics, and helps bridge the communication gap between layperson and scientist. 2) New codes can be devised when new species are described, allowing researchers to add the AMP# once it is assigned. 3) The basic system yields fewer shared codes than a system using the first two letters of the genus plus the first two letters of the specific epithet (for examples, see Corn 1994:116; Scott 1994:82). That system has 34 species sharing field codes, including three sets of triplets (e.g., AMMA = *Ambystoma mabeei*, *A. maculatum*, and *A. macrodactylum*). Fewer exceptions means fewer irregular codes to remember, which is important because the number of described amphibian species will exceed 5000 by the turn of this century (Glaw and Köhler 1998). 4) The code is based on scientific names and is responsive to systematic revisions. For example, elevating *Eurycea longicauda guttolineata* to specific status (Carlin 1997) required the new code EGUT for it, restricting ELON for *E. longicauda* (if EGUT had been taken, the new code for *E. guttolineata* would have been EGUL). Linking field codes to AMP# in the processing stage enables tracking of taxonomic changes, because the AMP# is also "meant to remain stable, linking old and new computer files without the worry of name and taxonomic changes" (U.S. Geological Survey 1999b). 5) The code has easy-to-apply rules, allowing its use with other faunas. My lab uses the same system for the reptiles, fishes, and aquatic macroinvertebrates that coexist with the 45 species of amphibians and reptiles in the Francis Marion National Forest, South Carolina, USA. 6) The alphabetic system recognizes that species are nominal variates, preventing them from being confused with continuous variates, as might be done with the AMP#. A researcher shouting out "RCAT, 6.9 total length " as he or she returns a bullfrog tadpole to the pond presents fewer numbers for the recorder to transpose than "#228, 6.9 total length."

The alphabetical field code presented here is intended solely to supplement the numerical code; herpetologists intending to share data should always include the AMP# in their files. Both AMP# and the "alpha" code discussed here are available on-line (U.S. Geological Survey 1999b). By adopting a uniform system of alphabetical field codes and linking it to AMP# in the processing stage, herpetologists can record data easily and with few errors in the field, simplifying accurate data gathering and enabling data transfer and linkage from diverse sources.

Acknowledgments.—Herpetology students at the College of Charleston forced me to devise codes they could remember in the field. I thank David Chalcraft and Jamie Schurbon for entering species names and codes into the computer. Chris Binckley, David Chalcraft, Stephen Corn, and Sam Droege made many helpful suggestions on the manuscript. This research was supported by EPA Grant R825795 (to W. J. Resetarits, Jr. and J. E. Fauth) and Challenge Grant 97-231 from the National Fish & Wildlife Foundation. The University of Illinois, the Illinois Natural History Survey, the E. J. Westfeldt-Bunting Foundation and the Gaylord and Dorothy Donnelly Foundation provided challenge funds. The views and conclusions contained in this document are those of the author and should not be interpreted as representing the opinions or policies of the U.S. Government. Mention of trade names or commercial products does not constitute their endorsement by the U.S. Government.

SSAR Auction of Joseph R. Bailey's Herpetological Library

Joseph R. Bailey, who died in 1998, was a leading expert on the snakes of tropical America and coauthor of the book "Amphibians and Reptiles of the Carolinas and Virginia" (University of North Carolina Press, 1980). He was professor of zoology at Duke University where he supervised many outstanding graduate and undergraduate students. A full obituary was published in *Herpetological Review* (vol. 30, pp. 70–71, June 1999).

Joe was also a staunch supporter of SSAR and joined the society in the late 1950s when it was still called The Ohio Herpetological Society. He attended many of its meetings, most recently at Appalachian State University, North Carolina, in 1995, and he regularly supported society projects involving students and books. It is most fitting, therefore, that his wife, Mike Bailey, has donated Joe's herp library to SSAR on the condition that it be auctioned and with the proceeds being used to continue Joe's interests in society activities. Accordingly, the Board of Directors of SSAR has gratefully accepted Mrs. Bailey's generous donation and decided to use the auction proceeds to set up in perpetuity The Joseph R. Bailey Endowment. The income on this investment will be used to support student activities, book-length publication projects, and other activities in keeping with Joe Bailey's interests. The Baileys' generosity will thus continue to be acknowledged in SSAR books and on student research papers, and be associated with other society activities that will be supported by the endowment.

Joe Bailey had an excellent herpetological library. Some of the books have been donated to the Duke library, but the bulk of the library—consisting of about 300 books—will be auctioned. The collection is especially rich on North and South American topics. A complete list can be obtained on request from Kraig Adler (*address*: Neurobiology and Behavior, Seeley G. Mudd Hall, Cornell University, Ithaca, New York 14853–2702, USA). **Please send a self-addressed mailing label with your request OR, better yet, send your e-mail address.** The auction will be conducted entirely via the post. Full auction instructions are given with this list. (Deadline for receipt of bids will be February 1, 2000).

Addenda to the Checklist of West Indian Amphibians and Reptiles

ROBERT POWELL
Department of Natural Sciences, Avila College
Kansas City, Missouri 64145–1698, USA
e-mail: powellr@mail.avila.edu

and

ROBERT W. HENDERSON
Section of Vertebrate Zoology, Milwaukee Public Museum
Milwaukee, Wisconsin 53233–1478, USA
e-mail: rh@mpm.edu

Hedges (1996a) presented a "discovery curve" of West Indian amphibians and reptiles that illustrated a recent sharp increase in the number of known herpetofaunal species. In fact, since the publication of the most recent checklist of West Indian species by Powell et al. (1996), a number of new forms have been described, reevaluated, or discovered for the first time in the region. In addition, one introduced species is removed from the list because it has not been encountered by herpetologists. With the exception that we now advocate the omission of squamate suborders (see Pough et al. 1998), we use the format of the 1996 checklist in providing all of the new records that have come to our attention.

Class Amphibia, Order Anura
Family Leptodactylidae

Eleutherodactylus blairhedgesi. *Eleutherodactylus blairhedgesi* Estrada, Díaz, and Rodríguez 1997:19. • CUB • Estrada, A. R., L. M. Díaz, and A. Rodríguez. 1997. Nueva especie de *Eleutherodactylus* (Anura: Leptodactylidae) del litoral norte de la Habana, Cuba. Rev. Esp. Herpetol. 11:19–24.

Eleutherodactylus casparii. *Eleutherodactylus casparii* Dunn 1926: 215. • CUB • Dunn, E. R. 1926. Additional frogs from Cuba. Occ. Pap. Boston Soc. Nat. Hist. 5:209–215. — Re-elevated from subspecific status by Estrada and Hedges (1997).

Eleutherodactylus iberia. *Eleutherodactylus iberia* Estrada and Hedges 1996: 853. • CUB • Estrada, A. R., and S. B. Hedges. 1996. At the lower size limit in tetrapods: a new diminutive frog from Cuba (Leptodactylidae: *Eleutherodactylus*). Copeia 1996:852–859.

Eleutherodactylus glamyrus. *Eleutherodactylus glamyrus* Estrada and Hedges 1997:365. • CUB • Estrada, A. R., and S. B. Hedges. 1997. A new species of frog from the Sierra Maestra, Cuba (Leptodactylidae, *Eleutherodactylus*). J. Herpetol. 31:364–368.

Eleutherodactylus goini. *Eleutherodactylus ricordi goini* Schwartz 1960: 19. • CUB • Schwartz, A. 1960. Nine new Cuban frogs of the genus *Eleutherodactylus*. Reading Pub. Mus. Art Gall., Sci. Publ. 11:1–50. — Elevated from subspecific status by Estrada and Hedges (1997).

Eleutherodactylus jaumei. *Eleutherodactylus jaumei* Estrada and Alonso 1997:41. • CUB • Estrada, A. R., and R. Alonso. 1997. Nueva especie de grupo *limbatus* (Leptodactylidae: *Eleutherodactylus*) de la región oriental de Cuba. Carib. J. Sci. 33:41–44.

Eleutherodactylus neodreptus. *Eleutherodactylus neodreptus* Schwartz 1965 was allocated to the synonymy of *E. audanti* Cochran 1934 by Hedges (1996b).

Eleutherodactylus principalis. *Eleutherodactylus principalis* Estrada and Hedges 1997:222. • CUB • Estrada, A. R., and S. B. Hedges. 1997. Nueva especie de *Eleutherodactylus* (Anura: Leptodactylidae) del Macizo Sagua-Baracoa, Cuba. Carib. J. Sci. 33:222–226.

Eleutherodactylus riparius. *Eleutherodactylus riparius* Estrada and Hedges 1998:222. • CUB • Estrada, A. R. and S. B. Hedges. 1998. Sistemática de las ranas rivereñas de Cuba (Leptodactylidae: *Eleutherodactylus*) con la descripción de una especie nueva. Carib. J. Sci. 34:218–230.

Eleutherodactylus sierramaestrae. *Eleutherodactylus sierramaestrae* Schmidt 1920 was allocated to the synonymy of *E. cuneatus* (Cope 1862) by Estrada and Hedges (1998).

Eleutherodactylus tetajulia. *Eleutherodactylus tetajulia* Estrada and Hedges 1996:436. • CUB • Estrada, A. R., and S. B. Hedges. 1996. A new frog of the genus *Eleutherodactylus* from eastern Cuba (Anura: Leptodactylidae). Herpetologica 52:435–439.

Eleutherodactylus tonyi. *Eleutherodactylus tonyi* Estrada and Hedges 1997:227. • CUB • Estrada, A. R., and S. B. Hedges. 1997. A new species of frog from the Meseta de Cabo Cruz, eastern Cuba (Leptodactylidae, *Eleutherodactylus*). Carib. J. Sci. 33:227–232.

Family Hylidae

Pseudacris crucifer. *Pseudacris crucifer* (Wied 1838) was believed to have been introduced to Cuba, but it has not been encountered by herpetologists and therefore should be removed from the checklist.

Class Reptilia, Order Squamata
Family Amphisbaenidae

Amphisbaena barbouri. *Amphisbaena cubana barbouri* Gans and Alexander 1962:97. • CUB • Gans, C., and A. A. Alexander. 1962. Studies on amphisbaenids (Amphisbaenia: Reptilia). 2. On the amphisbaenids of the Antilles. Bull. Mus. Comp. Zool. 128:65–158. — Elevated from subspecific status by Thomas and Hedges (1998a).

Amphisbaena carlgansi. *Amphisbaena carlgansi* Thomas and Hedges 1998:93. • CUB • Thomas, R., and S. B. Hedges. 1998. A new amphisbaenian from Cuba. J. Herpetol. 32:92–96.

Amphisbaena hyporissor. *Amphisbaena gonavensis hyporissor* Thomas 1965:5. • HISP • Thomas, R. 1965. Two new subspecies of *Amphisbaena* (Amphisbaenia, Reptilia) from the Barahona Peninsula of Hispaniola. Breviora (215):1–14. — Elevated from subspecific status by Powell et al. (1999).

Family Anguidae

Celestus badius. *Celestus badius* Cope 1868:126. • N • Cope, E. D. 1868. An examination of the Reptilia and Batrachia obtained by the Orton Expedition to Ecuador and the Upper Amazon, with notes on other species. Proc. Acad. Nat. Sci. Philadelphia 20:96–140. — Re-elevated from subspecific status by Powell (1999).

Diploglossus garridoi. *Diploglossus garridoi* Thomas and Hedges 1998:98. • CUB • Thomas, R., and S. B. Hedges. 1998. New anguid lizard (*Diploglossus*) from Cuba. Copeia 1998:97–103.

Diploglossus nigropunctatus. *Diploglossus delasagra nigropunctata* Barbour and Shreve 1937:378. • CUB • Barbour, T., and B. Shreve. 1937. Novitates Cubanae. Bull. Mus. Comp. Zool. 80:377–387. — Elevated from subspecific status by Thomas and Hedges (1998b).

Family Boidae

Corallus cookii. *Corallus Cookii* Gray 1842:42. • LA • Gray, J. E. 1842. Synopsis of prehensile-tailed snakes, or family Boidae. Zool. Misc. 1842:41–46. — Re-elevated from subspecific status by Henderson (1997); replaces, in part, *Corallus hortulanus*.

Corallus grenadensis. *Corallus grenadensis* Barbour 1914:327. • LA • Barbour, T. 1914. A contribution to the zoögeography of the West Indies, with especial reference to amphibians and reptiles. Bull. Mus. Comp. Zoöl. 44:209–359. — Resurrected by Henderson (1997); replaces, in part, *Corallus hortulanus*.

Family Colubridae

Thamnophis sauritus sackenii. *Eutaenia Sackenii* Kennicott 1859:98. • BAH • Kennicott, R. 1859. Notes on *Coluber calligaster* of Say, and a description of new species of serpents in the collection of the North Western University of Evanston, Ill. Proc. Acad. Nat. Sci. Philadelphia 11:98–100. — Presence of a waif (but not necessarily a breeding population) in the West Indies was recorded by Buckner and Franz (1998a).

Thamnophis sirtalis sirtalis. *Coluber Sirtalis* Linnaeus 1758:222. • BAH • Linnaeus, C. 1758. Systema Naturae per Regna Tria Naturæ, Secundum Classes, Ordines, Genera, Species, cum Characteribus, Differentiis, Synonymis, Locis. Tomus I. 10th ed. L. Salvius, Stockholm. — Presence of a waif (but not necessarily a breeding population) in the West Indies was recorded by Buckner and Franz (1998b).

Family Gekkonidae

Gekko gecko. *Lacerta gecko* Linnaeus 1758:205. • LA • Linnaeus, C. 1758. Systema Naturæ per Regna Tria Naturæ, Secundum Classes, Ordines, Genera, Species cum Characteribus, Differentiis, Synonymis, Locis. Tomus I. Editio decima. Reformata. L. Salvii, Holmiae. — Presence of a breeding population on Martinique confirmed by Henderson et al. (1993).

Sphaerodactylus pimienta. *Sphaerodactylus pimienta* Thomas, Hedges, and Garrido 1998:66. • CUB • Thomas, R., S. B. Hedges, and O. Garrido. 1998. A new gecko (*Sphaerodactylus*) from the Sierra Maestra of Cuba. J. Herpetol. 32:66–69.

Sphaerodactylus schuberti. *Sphaerodactylus schuberti* Thomas and Hedges 1998:333. • CUB • Thomas, R., and S. B. Hedges. 1998. A new gecko from the Sierra de Neiba of Hispaniola (Squamata: Gekkonidae: *Sphaerodactylus*). Herpetologica 54:333–336.

Sphaerodactylus storeyae. *Sphaerodactylus storeyae* Grant 1944:125. • CUB • Grant, C. 1944. New sphaerodactyls from Cuba and the Isle of Pines. Herpetologica 2:118–125. — Re-elevated from subspecific status by Hedges and Garrido (1993).

Tarentola albertschwartzi. *Tarentola albertschwartzi* Sprackland and Swinney 1998:73. • JAM • Sprackland, R. G., and G. N. Swinney. 1998. A new species of giant gecko of the genus *Tarentola* (Reptilia: Squamata: Gekkonidae) from Jamaica. J. Zool. Soc. London 245:73–78. — This taxon is based on a single specimen presented in 1884 to the collection of the National Museums of Scotland; the species possibly is extinct.

Family Iguanidae

Cyclura onchiopsis. *Cyclura onchiopsis* Cope 1885:1006. • N • Cope, E. D. 1885. The large iguanas of the Greater Antilles. Amer. Nat. 19:1005–1006. — Re-elevated from subspecific status by Powell (1999); this species is almost certainly extinct.

Cyclura stejnegeri. *Cyclura stejnegeri* Barbour and Noble 1916:163. • PRB • Barbour, T., and G. K. Noble. 1916. A revision of the lizards of the genus *Cyclura*. Bull. Mus. Comp. Zoöl. 60:139–164 + 15 pl. — Re-elevated from subspecific status by Powell (1999); see also Wiewandt (1982).

Family Polychrotidae

Anolis agueroi. *Chamaeleolis agueroi* Díaz, Navarro, and Garrido 1998:28. • CUB • Díaz, L. M., N. Navarro, and O. H. Garrido. 1998. Nueva especie de *Chamaeleolis* (Sauria: Iguanidae) de la Meseta de Cabo Cruz, Granma, Cuba. A new species of *Chamaeleolis* (Sauria: Iguanidae) from Meseta de Cabo Cruz, Granma, Cuba. Avicennia 8/9:27–34. — Although the authors explicitly state that they favor recognition of the genus *Chamaeleolis*, we continue to follow Hass et al. (1993), Hedges (1996), and Powell et al. (1996), who placed *Chamaeleolis* in the synonymy of *Anolis*.

Anolis garridoi. *Anolis garridoi* Díaz, Estrada, and Moreno 1996:54. • CUB • Díaz, L. M., A. R. Estrada, and L. V. Moreno. 1996. A new species of *Anolis* (Sauria: Iguanidae) from the Sierra de Trinidad, Sancti Spiritus, Cuba. Carib. J. Sci. 32:54–58.

Anolis incredulus. *Anolis incredulus* Garrido and Moreno 1998:36. • CUB • Garrido, O. H., and L. V. Moreno. 1998. Nueva especie de *Anolis* (Lacertilia: Iguanidae) del Pico Turquino, Sierra Maestra, Cuba. A new species of *Anolis* (Lacertilia: Iguanidae) from Pico Turquino, Sierra Maestra, Cuba. Avicennia 8/9:35–40.

Family Tropidophiidae

Tropidophis bucculentus. *Ungalia bucculenta* Cope 1868:129. • N • Cope, E. D. 1868. An examination of the Reptilia and Batrachia obtained by the Orton Expedition to Ecuador and the Upper Amazon, with notes on other species. Proc. Acad. Nat. Sci. Philadelphia 20:96–140. — Re-elevated from subspecific status by Powell (1999); this species is almost certainly extinct.

Tropidophis celiae. *Tropidophis celiae* Hedges, Estrada, and Diaz 1999:376. • CUB • Hedges, S. B., A. R. Estrada, and L. M. Diaz. 1999. New snake (*Tropidophis*) from western Cuba. Copeia 1999:376–381.

Tropidophis spiritus. *Tropidophis spiritus* Hedges and Garrido 1999: in press. • CUB • Hedges, S. B., and O. Garrido. 1999. A new snake of the genus *Tropidophis* (Tropidophiidae) from central Cuba. J. Herpetol. 33: in press.

Family Typhlopidae

Ramphotyphlops braminus. *Eryx braminus* Daudin 1803:279. • LA • Daudin, F.-M. 1803. Histoire Naturelle Générale et Particulière des Reptiles. Vol. 7. F. Dufart, Paris. — Presence in the West Indies was recorded by Censky and Hodge (1997).

Typhlops annae. *Typhlops annae* Breuil 1999:32. • LA • Breuil, M. 1999. Nouvelle espèce du genre *Typhlops*, (Serpentes, Typhlopidae) de l'île de Saint-Barthélemy, comparaison avec les autres espèces des Petites Antilles. Bull. mens. Soc. Linn. Lyon 68:30–40.

Acknowledgments.—S. Blair Hedges brought several new records to our attention and commented on an earlier draft of this manuscript. Jesús Ortea kindly provided copies of the new species descriptions that appeared in *Avicennia*. Kraig Adler, as he has on many other occasions, provided information on original descriptions.

Using the Internet to Establish the Status of an Easily Distinguished, Vulnerable Species, the Wood Turtle (*Clemmys insculpta*) in New Brunswick, Canada

DONALD F. MCALPINE
New Brunswick Museum, 277 Douglas Avenue
Saint John, New Brunswick E2K 1E5, Canada
e-mail: dmcalpin@nb.aibn.com

and

STEFEN H. GERRIETS
Atlantic Canada Conservation Data Centre
Box 6416, Sackville, New Brunswick E4L 1G6, Canada
e-mail: stefen.gerriets@ec.gc.ca

The wood turtle, *Clemmys insculpta*, is a terrestrial species that ranges discontinuously from Nova Scotia and New Brunswick south to Virginia and west through southern Quebec, southern Ontario, and New York, to northern Michigan, Wisconsin, eastern Minnesota, and northeastern Iowa (Litzgus and Brooks 1996). Over much of the species' range the wood turtle is now considered threatened, vulnerable, or even endangered, largely through habitat loss and collecting for the pet trade (Harding and Bloomer 1979; Litzgus and Brooks 1996). In New Brunswick the wood turtle is considered vulnerable (Heward and McAlpine 1994), however there have been no formal surveys of the species in the province. Although the wood turtle currently receives no protection under New Brunswick legislation, wildlife managers have flagged the species as of special concern and wood turtles and their riparian habitat are now routinely considered during environmental impact assessments.

Until recently, knowledge of the status of the wood turtle in New Brunswick was sketchy, and it remains incomplete. There are only 10 specimens in the New Brunswick Museum collection, acquired since 1966. With requests from provincial wildlife and environmental impact personnel growing, but no funds, personnel, or time for wood turtle surveys, it was decided to try soliciting observations via NatureNB, an Internet discussion group established 12 April 1996 and maintained by provincial naturalists. There are currently 257 subscribers. In the second and third years of operation the subscriber base grew by 39% and 30% respectively, and continues to grow (D. S. Christie, pers. comm.). Here we describe our success with this approach and review those circumstances where it may be applied usefully to other species.

Prior to 1997, when we placed our first request for information, wood turtle status in New Brunswick was based on the 10 specimens noted above, one specimen in the Canadian Museum of Nature, and two in the Royal Ontario Museum, and on a file of correspondence held at the New Brunswick Museum. The latter was partly the result of requests for information on the species published in naturalist's newsletters by Museum Curator, Dr. Austin Squires, in 1950 and 1968, plus a few observations provided by naturalists in conjunction with their regular bird sighting reports to the museum.

Our Internet requests netted 63 observations during the 1997 and 1998 field seasons. The approach has proven to be an effective, rapid, and low-cost method of acquiring data on this species; 34% of our 185 databased observations from 41 New Brunswick localities were Internet-solicited over only two field seasons (31.5 records/yr). By contrast, the remaining 122 (66%) observations, from 45 localities, were acquired over 48 years, starting in 1950 (2.5 records/yr). We have considered wood turtle locations as distinct if they are 1 km or more apart. The review of Litzgus and Brooks (1996) suggests wood turtles are relatively sedentary over a period of dec-

ades, moving over home ranges that may be little more than several hundred meters in diameter. However, lumping records that are in the same watershed and within 3 km of each other reduces the total number of localities only marginally, to 73. A specimen in the Royal Ontario Museum (ROM 2224) collected in 1925 has locality given only as New Brunswick and could therefore not be included in our analysis.

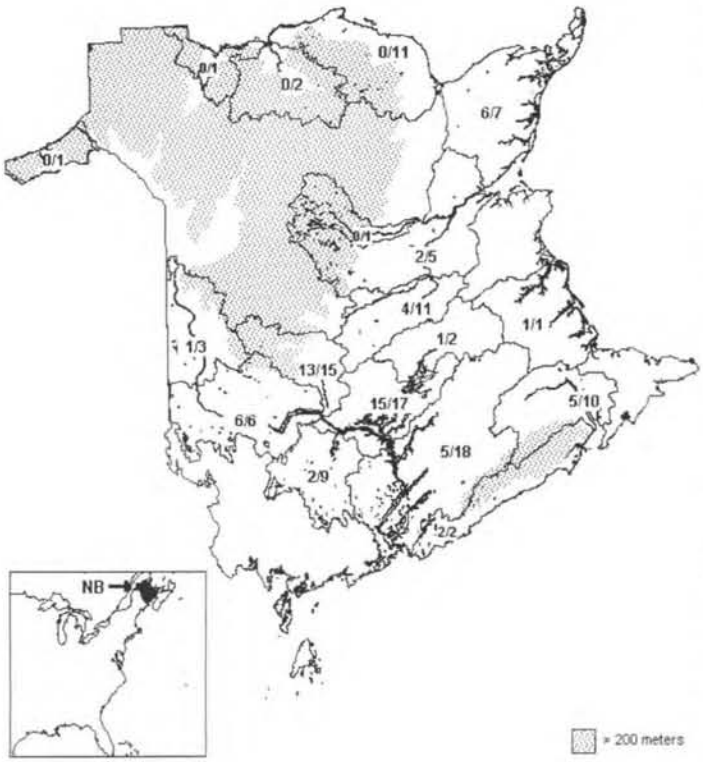

FIG. 1. Preliminary distribution of the wood turtle in New Brunswick. Records are mapped by tertiary watersheds showing the total number of Internet solicited wood turtle records/ and the total number of all other wood turtle records per watershed. Highland areas with elevations over 200 m are stippled.

Acquiring observations via the Internet has prompted us to prepare the first detailed distribution map for the wood turtle in New Brunswick, a region where the species reaches the northern limit of its range. In an effort to provide some protection for populations we have plotted records to tertiary watersheds only (Fig. 1). Data remain preliminary, but suggest that wood turtles are largely absent from highland areas which are present in the central and northwestern part of the province. Lack of records from the southwest is most likely due to the paucity of field work and observers in the region.

Some of the Internet observations are supported by photographs and several also have provided data on nesting periods. Many of the observations are repeat sightings from the same location. In our first year we also had many historical sightings reported, some dating back several decades. Historical and repeat sightings are valuable as they can help establish the persistence of populations, as well as help separate sightings based on transient or human displaced animals. We strongly suspect that some observations represent translocated wood turtles. Our inquiries in the future will be directed especially at trying to determine the distribution of breeding populations of wood turtles in New Brunswick.

Specialized Internet e-mail lists are growing in number. Several provinces and states now have such discussion groups organized for those with an interest in natural history. Although these e-mail lists are dedicated largely to reporting bird sightings, there are many experienced naturalists signed on who are regularly in the field and who are eager to contribute data to any natural history project. We have found that maximum interest can be generated in the following manner: 1) repeat the request for information annually, at the start of the field season, 2) post a summary of some of the most interesting reports at intervals through the season, 3) encourage respondents to report historical sightings or consult their field journals, 4) make personal contact via e-mail with all respondents, 5) post an annual summary at the end of each season in which respondents are noted by name.

Although this approach is not a substitute for in-depth study or detailed monitoring by field scientists, we believe it can help investigators in circumstances where the species of concern is easily identified and the distribution of the species is patchy, or the species is rare or hard to find.

In New Brunswick there are only three species of native freshwater turtles; the wood turtle, the painted turtle (*Chrysemys picta*), and the snapping turtle (*Chelydra serpentina*). Separating the species is straight-forward. Even if observers do not know the identity of the turtle species involved, a few questions from an investigator can quickly establish its identity. Additionally, we have encouraged observers to submit photographs of any turtle reported. These photos, along with written descriptive information, are archived in the New Brunswick Museum files. These files offer some degree of verifiability for observations. Wood turtles seem to be widespread in New Brunswick, although discontinuous in distribution. However, populations may be small and individuals are infrequently encountered. It is impractical for the few field herpetologists in New Brunswick to survey all suitable habitat. Soliciting observations from naturalists via the Internet has allowed us to overcome the opportunistic nature of wood turtle sightings in the region.

Acknowledgments.—We are grateful to each of the NatureNB subscribers who responded to our requests for wood turtle information. David Christie, co-owner of NatureNB, kindly provided information on the history and growth of this Internet discussion group. We thank Ross MacCulloch (Royal Ontario Museum) and Michèle Steigerwald (Canadian Museum of Nature) for details on wood turtle specimens in their collections.

Berkeley, California 94703, USA

Twinning in lizards has been recorded in a few species (Carpenter and Yoshida 1967; Shaw 1954). In this note we document twinning in three additional species of lizards—*Hydrosaurus pustulatus*, *Pogona vitticeps*, and *Varanus gouldii*—that have produced twin neonates at the Dallas Zoo Department of Herpetology. See Tables 1–2 for morphometric data.

In addition to lizards, twinning has been recorded in other reptiles, including turtles (Crooks and Smith 1958; Marion 1980; Tucker and Funk 1976; Yntema 1971), snakes (Gudynas and Gambarotta 1981; Shuette 1978; Singh and Thaphiyal 1973), and crocodilians (Bloomberg 1979). Twinning has also occurred with *Morelia viridis* (Siamese twins) and *Aspidites melanocephalus* (D. T. Roberts, pers. comm.) at the Dallas Zoo. In our experience the occurrence of twins in reptiles is uncommon, as only a few species have produced twin neonates in this institution's history.

Acknowledgments.—We thank the staff of the Dallas Zoo Department of Herpetology, C. M. Garrett, and three anonymous reviewers for their help in improving this manuscript.

TABLE 1. Clutch morphometrics for three species of lizards at the Dallas Zoo. Data for individual eggs containing twin embryos are in bold face type. Dates of hatching are indicated for each clutch. Standard deviation indicated in parentheses.

Species	Mean Diameter (mm)	Mean Length (mm)	Mean Mass (g)	No. of Eggs
Hydrosaurus pustulatus	24.7 (0.2)	50.0 (0.7)	17.8 (0.8)	4
17 January 1987	**25.0**	**52.0**	**19.3**	
Pogona vitticeps	16.5 (0.6)	28.3 (3.0)	3.8 (0.6)	17
1 March 1989	**17.5**	**25.5**	**4.3**

A Comparison of Defensive Behavior in the African Colubrid Snakes *Hapsidophrys smaragdinus* and *Philothamnus irregularis*

PHIL SENTER
Department of Biological Sciences, Northern Illinois University
DeKalb, Illinois 60115, USA
e-mail: beccafaye@worldnet.att.net

Hapsidophrys smaragdinus and *Philothamnus irregularis* are slender, green, arboreal colubrids from tropical Africa. From 1984 to 1989, I collected four *H. smaragdinus* and six *P. irregularis* in Liberia, and noted their respective behaviors. Each species exhibited a characteristic suite of defensive behaviors, much of which is unrecorded in the literature.

Neck Inflation.—Both *H. smaragdinus* and *P. irregularis* inflate the neck when approached or grasped. Documentation of this behavior exists for *P. irregularis* (FitzSimons 1970; Pitman 1974; Sweeney 1961), but is missing in works that mention *H. smaragdinus* (e.g., Cansdale 1961; Pitman 1974; Villiers 1950).

In both species, neck inflation results in the display of a three-colored pattern. The dorsal scales are grass-green in both species. When the neck is inflated, the black interstitial skin becomes visible, as do light-colored spots. In *H. smaragdinus*, these spots are light blue and occur on every-other dorsal scale. In *P. irregularis*, the spots are white and occur on each dorsal scale.

Neck inflation in these species is probably an anti-predator device, as it was observed only in response to the approach or grasp of a human. The resulting increase in neck diameter is slight in these species; therefore, the predator-deterring element in the display is probably not size increase. If a predator is deterred by the display, this is more likely due to startling or confusion caused by the sudden appearance of the three-colored pattern.

Hapsidophrys and *Philothamnus* are sister groups (V. Wallach, pers. comm.). Their common neck-inflating defense display is therefore probably an example of behavioral homology.

Gaping and striking.—Philothamnus irregularis tends to gape widely while employing the neck inflation display. This adds more color to the display, because it showcases the iridescent blue tongue and the shiny, black interior of the mouth. The gape is no empty threat, as these snakes usually strike repeatedly. Pitman (1974) records gaping and striking behavior in this species, and FitzSimons (1970) considers *P. irregularis* "aggressive." Neither author, however, mentions the display of oral and lingual color during the gape.

Hapsidophrys smaragdinus is singularly nonaggressive. One individual bit me when I seized it by the tail; however, this occurred but once, and none of the other three *H. smaragdinus* struck at all. None of the four specimens that I observed employed a gaping display.

Shimmying.—One of the *P. irregularis* exhibited a behavior which could be described as "shimmying." As the snake explored its cage, it slid around with its neck raised and its head slightly cocked forward. After every two to five cm, the snake would pause and throw lateral undulations up its neck toward the head. This appeared to be a simulation of grass in the breeze. Identical behavior has been recorded in *Philothamnus semivariegatus* (Marais 1992), *Dispholidus typus* (Marais 1992), and *Thelotornis capensis* (Sweeney 1961). In the latter two species, the shimmy is associated with the stalking of prey (Marais 1992; Sweeney 1961). The *P. irregularis* which I observed was not stalking prey, and was perhaps engaging in a form of predator-eluding camouflage.

Other defensive behaviors.—The samples of both species included individuals that would freeze when first approached, then flee if the approacher did not move away. Other individuals of both species fled from the first approach, rather than freezing.

Three of the four *H. smaragdinus*, if grasped in the hand, would roll about the body's longitudinal axis in an apparent attempt to escape the grasp. This behavior did not occur in the sample of *P. irregularis*.

Acknowledgments.—I thank Earl and Ken Williams and the Yeanay family of Yekepa, Nimba County, Liberia, for helping me to locate and capture several of the snakes used in this study. I also thank the three couples who allowed me to temporarily house the specimens under their garage or porch roofs: Jim and Jane Park, John and Marie Taylor, and my parents, George and Libby Senter. I thank Robyn Senter, Richard Seigel, Van Wallach, and anonymous reviewers for constructive comments about this manuscript. Thanks also to Mata S. for her patronage.

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 2000 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson

2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include in-situ behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.

3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on an herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president.

5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.

6. INTERNATIONAL. Proposals may address needs in any of the above five categories, but applicants must be from countries where herpetological research has historically been underfunded, and where alternative sources of financial support are scarce or nonexistent.

7. BIBLIOGRAPHIC RESEARCH. This is a special category for 2000, thanks to a donation from Itzchak and Carolyn Gilboa. Proposals should address a major need to consult library or other information resources. The project must focus on a herpetological topic. Proposals from individuals only, accompanied by a letter of support from someone knowledgeable about the applicant and about the importance of the project.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR with the exception of those applying for support of regional herpetological society projects, or those applying in the international category. Membership dues must be paid (to SSAR Treasurer) no later than 31 December 1999 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. Past recipients of an SSAR GIH award in any category are not eligible for future awards. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) TITLE PAGE giving the title of the project, the name, mailing address, office and home telephone numbers and, if possible, fax number and e-mail address of the applicant. The title page should include a statement indicating that applicants "will comply with all applicable permit regulations, and adhere to all appropriate animal care guidelines in the course of conducting funded projects." (B) BACKGROUND AND OBJECTIVES of the proposed project. (C) METHODS of carrying out the project. (D) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). Include an explicit explanation of how an SSAR award of $500 would be applied toward the objectives of the project, and provide a listing of all current and pending support for the project. (E) BRIEF RESUMÉ of the applicant or project coordinator. (F) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed 1200 words, excluding title page, literature cited, resumé, and budget. Applicants must indicate word count on their application.

Applicants must designate to which of the seven categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than **31 DECEMBER 1999** to be considered. Failure to meet these guidelines may result in elimination of a proposal from consideration. The awards will be announced on or around 1 April 2000. Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Joseph R. Mendelson III, Chair, SSAR Grants-in-Herpetology, Department of Biology, Utah State University, Logan, Utah 84322-5305, USA. Tel. (435) 797-2097; Fax (435) 797-1575; e-mail: sapo@biology.usu.edu.*

RECENT POPULATION CHANGES

Distribution Records of *Rana virgatipes* and Associated Anuran Species along Maryland's Eastern Shore

MAC F. GIVEN
Division of Arts and Sciences, Neumann College
One Neumann Drive, Aston, Pennsylvania 19014-1298, USA
e-mail: mgiven@neumann.edu

Status assessments of rare species are required in our managed urban and rural landscapes. The inventory and monitoring programs of amphibians, in particular, are needed due to declining populations issues unique to this fauna (Blaustein 1994; Phillips 1994; Sarkar 1996). Historical data, when available, provide a basis for examining recent population trends (Lips 1998; Pechmann and Wilbur 1994). In Maryland, the anuran *Rana virgatipes*, the carpenter frog, is of concern. The species has a range along the east coast of the U.S. from southern New Jersey to Georgia. While abundant in some states such as New Jersey, it is classified as threatened in Maryland. According to historical records, populations have been observed at 22 Maryland sites, all but one on the East Shore of the Chesapeake Bay. The primary purpose of this study was to revisit these historical sites and assess the current status of these populations.

The scope of this study was expanded in light of the general need for baseline data so that declines of amphibian populations can be documented. First, I collected additional data at each site, including the presence/absence of other anuran choruses, measurements of water pH, and qualitative descriptions of habitat. pH measurements from the habitats of natural populations have become an important supplement to baseline population data. For example, laboratory experiments suggest synergistic interactions between pH and other environmental parameters that may determine anuran distributions and account for some of the population disappearances (Beattie and Tyler-Jones 1992; Bradford et al. 1992; Brodkin et al. 1992). I also examined likely additional habitats that were along my travel routes or in close proximity to the historical sites.

Methods.—In 1990 the Wildlife and Heritage Division of the Maryland Department of Natural Resources supplied topographic maps showing locations of 22 sites with historical records of *R. virgatipes*. These were distributed among seven counties, all but one on the Eastern Shore of the Chesapeake Bay. I visited all of these sites plus 12 additional sites, one to three times each, between 23 May and 17 July 1990 (Table 1). The additional sites included observations of wetlands along my travel routes and close to historical sites that appeared to have suitable *R. virgatipes* habitat. In addition, Bill Grogan (Salisbury State University), who has published site locations for *R. virgatipes* (Grogan 1974), suggested two additional sites where he was confident that I would find choruses: Big Mill and Swans Gut Ponds. Multiple visits were made whenever possible; once the exact location of a site was known, it was convenient to make observations en route to a more distant site. Copies of mapped locations are available at the Wildlife and Heritage Division of the Maryland Department of Natural Resources and can be obtained by contacting Katharine McCarthy, Tawes State Office Building E-1, 580 Taylor Avenue, Annapolis, Maryland 21401, USA.

I used the following protocol. During daylight hours, I located and photographed sites, and measured surface water pH and temperature. I measured pH with a Whatman pH μ-Sensor (Cat. No. 6240-0000), calibrating with standardized buffer solutions. Consistency of these data was supported in 1994 when I remeasured pH at three sites; measurements were either identical (two sites) or within 0.4 pH units (one site) of the 1990 measurements. I also made a qualitative assessment of the habitat. First, was the water in the habitat best characterized as a pond, stream, or estuary? Second, what was the general abundance of emergent vegetation? Third, was the site in a headwater region and if so, was it separated from agricultural fields by a forest or other vegetational buffer?

At night, I returned after 2100 h (EDT) to estimate the number of male *R. virgatipes* calling (categories: none, <6, >12, >25 and >100). Other calling anuran species were noted and later confirmed by listening to tape recordings taken at each site. Recordings were made with a Superscope EC-33S microphone and Marantz PMD430 stereo cassette recorder, and are kept by the author.

To study patterns among all of the species surveyed, I conducted a test of association (Ludwig and Reynolds 1988) on the presence/absence of seven anuran species at the 34 sites. Two species were excluded from analysis: 1) *Rana clamitans* because it was present on all but one site and 2) *Pseudacris crucifer* because it was observed only once (most breeding in this species occurred before my survey began). *Hyla versicolor* and *Hyla chrysoscelis* were treated as one species; given the range of temperatures experienced in the field, they could not always be distinguished from each other (although both species were observed along the roadside near Pristine Pines).

Results.—Only 9 *R. virgatipes* populations were identified: 8 of 22 historical localities, and 1 of 12 additional sites (Table 1). The one new site, Pristine Pines North, was within a kilometer of two historical sites that still have *R. virgatipes* present (Pristine Pines and Pristine Pines South). The *R. virgatipes* populations were located in Queen Anne, Caroline, and northern Dorchester counties; populations were not found in Charles, Talbot, southern Dorchester, or Worcester counties despite historical records. All of these populations were in pond habitats in headwater regions, separated from agricultural fields by forest or other vegetational buffers. Males called from shallow water with abundant emergent vegetation. Most of the populations were small; the two largest choruses were found at Baltimore Corners 3 (>100 calling males) and Johnson Road Pond (25–50 calling males).

Rana virgatipes appears to be acid tolerant; six of the populations were in acidic water with pHs ranging from 3.6 to 4.2 (Table 1). The only population in markedly less acidic water, with a pH of 5.6, was at Pristine Pines South. This site had the smallest number of calling males (fewer than six on three separate visits), suggesting that their presence may be explained by emigration from two neighboring populations with more suitable habitat (Pristine Pines and Pristine Pines North). *Rana clamitans* showed the greatest range of acid and habitat tolerance; it was present in all but one site surveyed.

The test of association demonstrated a positive association between *R. virgatipes* and the southern leopard frog, *Rana utricularia* ($P < 0.01$ with Yate's correction). This means that populations of these species were more likely to occur together than if their distributions were random. There were no other significant associations.

My observation of a morph of *R. utricularia* similar to *R. virgatipes*, coupled with the association between these two species, suggests a potential source of error in the historical records. Typically, the back of *R. utricularia* is a patchwork of brown and green with large dark spots. I caught several with entirely brown backs and small dark spots, a pattern similar to *R. virgatipes*. However, these specimens had several *R. utricularia* characteristics: pointed snout, white ventrum, copper coloration on the lateral sides of the

TABLE 1. Species composition, *R. virgatipes* population estimates, and pH of sites visited in 1990. Notes: [1] *R. virgatipes* heard to the south, not at this specific site. [2] One male may have called once on 6/1; presence of species unlikely. [3] *R. virgatipes* heard in south pond; pH measurements taken from two locations near this pond. [4] Measurement taken 6/13/94. [5] Measurement taken from location near this pond; actual pond not found.

abdomen, and a yellow spot in the middle of each tympanum. Thus, any historical record not based on vocalizations may have involved the misidentification of *R. utricularia*.

Discussion.—*Rana virgatipes* populations were found at only nine sites on the East Shore of Maryland. This species apparently needs a habitat consisting of partially submerged vegetation in the permanent, acidic water of glades/potholes of headwater regions. This is consistent with studies of New Jersey populations (Given 1987, 1988a), where males called from clumps of partially submerged vegetation either along the banks of ponds or in the shallow water of cranberry bog reservoirs. The apparent association of *R. virgatipes* with low pH may confine their distribution to areas protected from large amounts of runoff. For example, ponds bordering agricultural fields and large streams tended to be less acidic than habitats with *R. virgatipes* populations (pers. observ.). The association of *R. virgatipes* with low pH is also consistent with data which showed that their eggs and tadpoles develop in acidic water that is lethal to many other species (Gosner and Black 1957). This may allow *R. virgatipes* to use acidic ponds as refuges from less tolerant competitors and predators (Freda and Dunson 1986; Freda and Taylor 1992).

Rana clamitans was found at all but one site and may be in the process of displacing *R. virgatipes* populations. In New Jersey, *R. virgatipes* is the most numerous ranid species of acidic cranberry bog reservoirs (pers. observ.), presumably due to *R. clamitans* being less acid tolerant (Gosner and Black 1957). In contrast, all of the Maryland sites with *R. virgatipes* present had much larger populations of chorusing *R. clamitans*. One study of behavioral interactions suggests that *R. clamitans* males displace *R. virgatipes* males (Given 1990). Males of both species chose similar microhabitats for calling sites which they vigorously defended from conspecifics. A playback experiment showed that male *R. virgatipes* respond

to *R. clamitans* advertisement calls with aggressive calls. However, because *R. virgatipes* males are smaller and unable to displace their heterospecific opponents, they eventually move to another calling site. The populations at Kane Crossroads Pond in this report may be an example of this type of interaction. *Rana clamitans* were numerous and distributed throughout the wetland site; calling *R. virgatipes* were restricted to a small island of habitat that was surrounded and greatly outnumbered by calling *R. clamitans* (pers. observ.).

I was especially concerned about my inability to find *R. virgatipes* choruses in southern Dorchester and Worcester counties, including the additional sites suggested by Bill Grogan. It is possible that some of these sites may have become seriously degraded. In the Delaware Wildlands, what was described as a sphagnum bog in 1948 (Meanley 1951) was no longer a bog (at least based on the map location provided to me); the area also had piles of trash and animal remains. The Nassawango Creek area was noteworthy in that there was very little chorusing activity of any anuran species. A second possible explanation is that *R. virgatipes* never was in these counties and were misidentified, perhaps due to the similarities in appearance of *R. virgatipes* and *R. utricularia* discussed earlier.

A third, less likely explanation, is that the breeding season of *R. virgatipes* may have begun and ended earlier at these more southern sites. In New Jersey, breeding seasons began in late April and continued until late July–early August (Given 1988b). In addition, the population at Cedar Run Lake, New Jersey, chorused from dusk to dawn except for a few early May nights when the air temperature approached freezing, and some marked individuals called every night (Given 1988b). Thus, if a chorus existed at a Maryland site and exhibited behavior similar to New Jersey populations, it should have been heard at any time on nights from May through July. Consistent with this, the six Maryland sites with *R. virgatipes* present that were visited more than once always had choruses present. For example, choruses were present at Pristine Pines and Pristine Pines South on all three visits (24 May, 1 June, and 20 June). Thus, if *R. virgatipes* exists in southern Maryland, my failure to find it can be explained if the breeding season had ended by mid-May.

Given that there are fewer populations of *R. virgatipes* in Maryland than the historical record suggests and that most of these populations are small, continuation of their threatened status is recommended. Fortunately, several populations are on land owned by the Nature Conservancy (Baltimore Corners 2 & 3, Johnson Road Pond, and Pristine Pines), suggesting that there are other distinctive flora and fauna that already have brought these areas to the attention of naturalists. It is unclear, however, if such small populations are sustainable long-term. These populations should continue to be monitored with special attention to pH fluctuations and to abundances of *R. clamitans*. In addition, given the positive association between *R. virgatipes* and *R. utricularia*, a more exhaustive survey should include historical *R. utricularia* sites in the hope of finding more populations of *R. virgatipes*.

Acknowledgments.—I appreciate the residents of Maryland who, without exception, welcomed a stranger on their properties. I had several helpful conversations with Bill Grogan and Katharine McCarthy. Funding was provided by the Maryland Natural Heritage Program. C. Bevier reviewed an earlier draft of this manuscript.

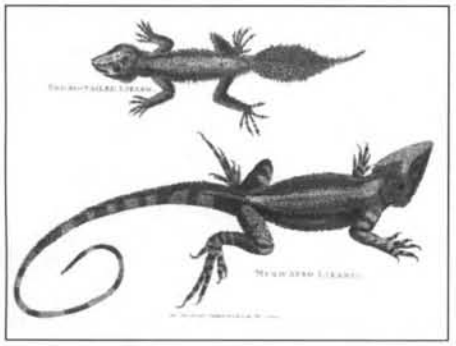
GEORGE SHAW'S "GENERAL ZOOLOGY"

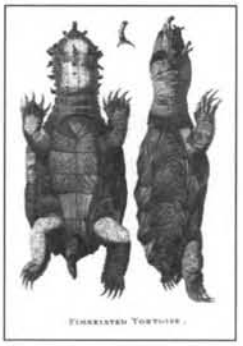
THE FIRST WORLD SUMMARY OF AMPHIBIANS AND REPTILES IN ENGLISH

With a Systematic Review of Shaw's Nomenclature by Hobart M. Smith and Patrick David

GEORGE SHAW (1751–1813), an English naturalist who became Keeper of Zoology at the British Museum, is one of the most familiar names in herpetology. His volume on amphibians and reptiles in his series "General Zoology" comprises the first world review of herpetology in English. Shaw's book, published in 1802, covered 432 species which represent a large fraction of the species known at the time. Of these, Shaw described 109 as new and two dozen of his taxa survive, including some of the most familiar species in the world: *Ambystoma maculatum, Rana catesbeiana, Caecilia gracilis, Geochelone radiata, Ctenosaura acanthura, Python regius,* and *Bitis nasicornis*. The text includes scientific and common names, extensive references to previous literature, natural history, and useful historical information. The 141 plates (see the samples at the bottom of this page) are typical of the era: excellent likenesses at their best, but sometimes amusing, fanciful, or even purloined from other works. Taken together, the text and plates represent an authoritative and classic survey at the start of the century during which herpetology became a science.



Hobart M. Smith (Boulder) and Patrick David (Paris) provide an extensive introduction in which Shaw's species are correlated with modern taxa. Many of Shaw's names have not been previously synonymized. They also provide a comprehensive index to Shaw's names.



Specifications: *about 975 pages, 141 plates, format 6 x 9 inches (15 x 23 cm), clothbound, ISBN 0–916984–48–6. To be published November 1999.*

In recent years, a number of turtle species have been designated at risk. The Committee on the Status of Endangered Wildlife in Canada (COSEWIC) currently lists five turtle species: leatherback turtle (*Dermochelys coriacea*; endangered), eastern spiny softshell turtle (*Apalone spinifera*; threatened), Blanding's turtle (*Emydoidea blandingii*; threatened), spotted turtle (*Clemmys guttata*; vulnerable), and wood turtle (*Clemmys insculpta*; vulnerable), with seven additional species yet to be assessed.

Molecular genetics has provided an increasingly valuable tool in gathering information germane to conservation status and management plans (Lambert and Millar 1995; Moritz 1995; Prior et al. 1997). The development of highly variable genetic markers (for review see O'Reilly and Wright 1995) and the polymerase chain reaction (PCR; Mullis et al. 1986) allows examination of population genetic structure at fine spatial and temporal scales as well as examination of relatedness and parentage, using very small amounts of DNA.

In adult turtles, DNA can be obtained non-destructively from blood samples. However, hatchling freshwater turtles are often too small to be effectively sampled by drawing blood. Toe clipping, which yields DNA in amphibians (Gonser and Collura 1996), is undesirable in turtles as claws are used in mating for both titillation and mounting. Blood has been collected from both the dorsal cervical sinus and the occipital sinus in sea turtle hatchlings (Wibbels et al. 1998 and references therein), however these sinuses either do not exist or are insufficiently developed in freshwater turtles to use as a blood sampling site. Until now, DNA could be obtained from hatchling freshwater turtles in two ways: sacrifice the hatchlings (see Galbraith 1993) or raise hatchlings in captivity until they are large enough for blood sampling (Mockford et al. 1999). We describe here a non-destructive source of DNA from hatchling turtles for use in PCR-based assays.

As part of the monitoring program of the Nova Scotia population of Blanding's turtle (*Emydoidea blandingii*) newly emerged hatchlings are given nest-specific marks (Herman et al., in press). Marking is done by notching up to three marginal scutes (Standing et al. 1995), from each of which a small fragment of carapace (approximately 2 mm^2) is removed. The underside of these carapace fragments is not yet ossified bone, and serves as our source of DNA.

Scutes are notched using a nail clipper and resulting fragments are placed in 1 ml of 70% ethanol at collection and stored at –20°C for up to one year. Nail clippers are rinsed in 100% ethanol and allowed to air dry between samples. Prior to extraction, individual fragments are removed from the ethanol and rinsed in 50µl high TE (100mM Tris-base, 40mM EDTA, pH 8.0) for approximately one minute, then placed in 25µl extraction buffer (10mM Tris-base [pH 8.3], 50mM KCl, 0.8% Tween 20) to which 2.5µl of Proteinase K (1mg/ml) has been added. The extraction buffer is incubated at 45°C overnight, and subjected to centrifugation at 11000 g for 1 minute. 20µl of the supernatant is pipetted into a new tube. We use the undiluted product of this crude extraction in PCR reactions for microsatellite assays.

While this crude extraction can be used directly, the DNA is likely contaminated with proteins (A260/A280 < 1.0) and may not be stable for long term storage. Where longer storage is desired DNA can be precipitated in 1/10 volume 3M sodium acetate and 2 volumes cold 100% ethanol. Following precipitation and resuspension in 25µl TE the average yield per fragment was 3.02µg (SE 1.02, N = 12; Beckman DU-64 spectrophotometer) with an A260/A280 of 1.56 (SE 0.22, N = 12). The comparison of absorbance at 260nm and at 280nm provides a measure of the purity of the DNA; pure DNA = 1.8.

Seventy-eight percent of samples were successfully PCR amplified in the first attempt from the crude extraction, and this did not improve following precipitation. Subsequent PCR reactions of the remaining samples required adjustment of the DNA concentration. This protocol has been used in a variety of tissue types including muscle tissue (McConnell et al. 1995) and fish eyeballs (Ruzzante et al. 1996) with similar results (D. Cook, pers. comm.).

As molecular genetics continue to be integrated into conservation biology the need for non-destructive sampling techniques increases. The technique described here has been used to sample hatchlings as small as 6.1 g with carapace lengths as short as 30 mm. While we have only used this technique on samples from Blanding's turtles, similarity in carapace anatomy suggests that this technique will work with many freshwater turtle species.

Comparing the Use of Pitfall Drift Fences and Cover Boards for Sampling the Threatened Sand Skink (*Neoseps reynoldsi*)

The sand skink (*Neoseps reynoldsi* Stejneger) is a fossorial lizard found only in xeric upland habitats (sandhill, scrub, scrubby flatwoods) in central Florida, USA. It is a small species, adults typically are only 100–130 mm in total length, and it displays a variety of morphological characters probably related to a fossorial existence. Among these characters are small limbs, lateral grooves to accept limbs during subsurface locomotion ("sand swimming"), wedge-shaped head, subterminal jaw, and small eyes.

The sand skink is a federally threatened species, with poorly-understood patterns of distribution and abundance among habitats (Campbell and Christman 1982a; Christman 1992; Cooper 1953; McCoy et al. 1999; Myers and Telford 1965; Telford 1959; U.S. Fish and Wildlife Service 1993). The development of precise methods for recognizing patterns of distribution and abundance is vital to its recovery (U.S. Fish and Wildlife Service 1993). A first step in developing such methods is to compare how well different sampling techniques detect its presence and accurately reflect its abundance. We compared two common herpetological sampling techniques, pitfall drift fences and cover boards.

Recent studies of the sand skink have used pitfall drift fences almost exclusively (e.g., Andrews 1994; McCoy and Mushinsky 1994; McCoy et al. 1999; Mushinsky and McCoy 1995). Pitfall drift fences are effective in capturing individuals, but they are relatively expensive to construct and maintain. Cover boards (Grant et al. 1992), on the other hand, are relatively inexpensive to construct and maintain, but are not as effective as pitfall drift fences in capturing individuals. Although individuals occasionally may be found under cover boards and other kinds of ground cover, they are not constrained to remain there. The fact that they do not constrain individuals may not necessarily be a shortcoming of cover boards, however, in many studies of the sand skink.

We compared the relative effectiveness of the two sampling techniques at seven sites, all of which were in scrub habitat and were known from preliminary surveys to harbor the sand skink (McCoy et al. 1999). We had little a priori information about the abundance at the seven sites, which made it difficult to decide how many cover boards and pitfall drift fences to install. We settled on a density of 1 cover board per 100 m^2 (a total of four cover boards at each site), based on previous studies. This density is lower than the density recommended for intensive field studies (e.g., Fellers and Drost 1994), but higher than the density employed in previous comparative studies (e.g., Campbell and Christman 1982b; Grant et al. 1992). We installed pitfall drift fences at a four-fold higher density than cover boards (a total of 16 at each site). Although matched numbers of cover boards and pitfall drift fences at each site would have provided a parsimonius experimental design, we installed additional pitfall drift fences to provide the higher level of trapping intensity that we thought would be required to estimate overall activity and reflect total abundance accurately (see below).

A pitfall drift fence consisted of a 2 m length of aluminum flashing with two 3.8 L buckets countersunk at each end, so that individuals diverted by the fence fell into the buckets. The combined lengths of the 16 drift fences at a site approximately equals the combined lengths of the four drift fences in a standard pitfall drift fence array (Campbell and Christman 1982b), but the number of pitfall traps is quadrupled. We assumed that the increase in the number of traps per meter of drift fence would increase the chance of capturing individuals of the small sand skink. Pitfall drift fences were centered on 16 stakes, evenly spread over a 20 m x 20 m area. Drift fences were buried to a depth of 30 cm, to ensure that individuals would not pass under them. Buckets were countersunk to depths between 3 cm and 8 cm below ground surface. The bottom of each bucket was perforated with at least ten 0.32 cm holes to promote drainage, and a lid was positioned over the bucket on clothespin supports to provide shade. We placed a layer of sand, at least 5 cm deep, in each bucket to provide substrate for burrowing.

A cover board consisted of a 1.27 cm-thick piece of plywood, 60 cm x 60 cm, which is intermediate in size to those used in most previous studies, 30 cm x 30 cm to 66 cm x 133 cm (Fellers and Drost 1994; Grant et al.1992). One cover board was placed at random within each quarter of the grid created by the pitfall drift fences at a site. The area where a cover board was placed was gently raked to bare sand and then leveled, so that the cover board rested on the ground at all points. In a few places where roots were at the surface, sand was added to create a uniform sandy surface under a cover board.

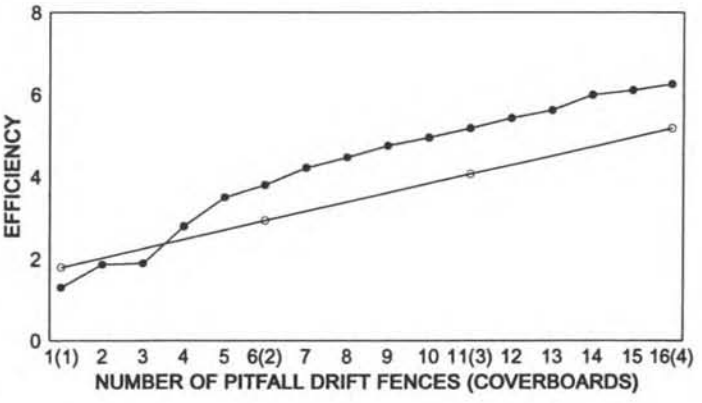

FIG. 1. Efficiency of detection (reciprocal of number of days to detect presence x 100) for 1–4 cover boards (open circles) and 1–16 pitfall drift fences (closed circles).

Pitfall drift fences were checked for captured individuals and the sand under cover boards was checked for the characteristic sinusoidal patterns that the sand skink leaves behind as it moves ("tracks"). Pitfall drift fences and cover boards were checked every 5–7 days during the potential peak activity period (14 weeks from February to mid-May), the summer (two weeks in July), and the early autumn (three weeks in September), 1995. Because we could not check the pitfall drift fences any more often, captured individuals could have been exposed to high rates of predation (Gibbons and Semlitsch 1981). That the lids positioned over the buckets were disturbed only twice, and only at one of the arrays near the end of the study, indicates that predation by the most likely predator, the racoon, probably was not an important source of mortality. We marked each individual captured by the pitfall drift fences with a hand-held cauterizer (McCoy et al. 1999), held it for one week to ensure that it was not harmed by the marking, and then released it near where it was captured. Initially, we tried to count tracks under cover boards, but we were unable to distinguish individual tracks when many of them were packed together, so we simply recorded the presence/absence of tracks.

We compared the data obtained from pitfall drift fences (individuals) and from cover boards (tracks) in four ways. Because of the difference in numbers of cover boards (4) and pitfall drift fences (16) at each site, direct comparisons would be misleading; therefore, we made probabilistic comparisons. The first comparison determined which technique detected presence of the sand skink at more sites. We counted the number of pitfall drift fences that detected no individuals at a site and then used a hypergeometric distribution to calculate the probability that any four pitfall drift fences selected at random would have detected no individuals. The second comparison determined which technique detected presence of the sand skink in the shorter time ("efficiency"). We used a randomization procedure: (1) select subsets of pitfall drift fences (1, 2...15 drift fences) or cover boards (1, 2, 3 cover boards) at random from each of the seven sites; (2) for each subset, locate the drift fence or cover board at each site that first detected presence; (3) record the number of days required to detect presence; (4) repeat 100 times; (5) calculate the mean of the 100 replicates for each site; (6) calculate the grand mean for all sites; (6) compare the grand means for pitfall drift fences and cover boards. The third comparison determined which technique reflected overall activity (number of captures by all 112 [= 16 pitfall drift fences per site x 7 sites] pitfall drift fences per week) more closely. We correlated (Spearman's Rank Correlation) cumulative (summed over all seven sites) number of captures per week by four randomly selected pitfall drift fences (ten replicates), and cumulative number of cover boards with tracks per week, with overall activity. We included this comparison in response to concern that tracks under cover boards might not represent levels of activity well, because cover boards may not be completely passive samplers (i.e., they may attract individuals of the sand skink by altering the microclimate of the soil or promoting unusually high densities of prey or cover) (Grant et al. 1992). The fourth comparison determined which technique reflected total abundance (number of individuals captured by all 16 pitfall drift fences at a site over the 19 weeks of the study) more closely. We correlated (Spearman's Rank Correlation) cumulative (summed over 19 weeks) number of individuals captured by four randomly selected pitfall drift fences (ten replicates), and cumulative number of cover boards with tracks, with total abundance.

Cover boards and pitfall drift fences proved to be about equally capable of detecting presence of the sand skink, but cover boards were more efficient at doing so. Four cover boards detected presence of the sand skink with certainty at all seven sites. In fact, only two of the 28 cover boards never had tracks under them. Four pitfall drift fences detected presence of the sand skink with virtual certainty at four of the seven sites; probabilities of detection at the other three sites were 0.98, 0.96, and 0.73. Although cover boards tended to be a more efficient technique for detection than pitfall drift fences with relatively low trapping effort (Fig. 1), the tendency could be confirmed only marginally. The median number of days required for at least one of four pitfall drift fences per site to detect presence of the sand skink was 21 (range = 7–63), and for at least one of four cover boards per site, it was 14 (range = 2–56) ($W = 63$, $P = 0.10$, N = 7/7). Even with much greater trapping effort, pitfall drift fences tended to be only about equally as efficient as cover boards (Fig. 1). The median number of days required for at least one of 16 pitfall drift fences per site to detect presence was 14 (range = 7–28) ($W = 53$, $P = 0.50$, N = 7/7). Increasing the number of pitfall drift fences from four to 16, to match the efficiency of four cover boards, comes at substantial cost, however. We estimated the cost of each pitfall drift fence to be US $11.43, including materials and labor, but the cost of each cover board to be only US $2.17.

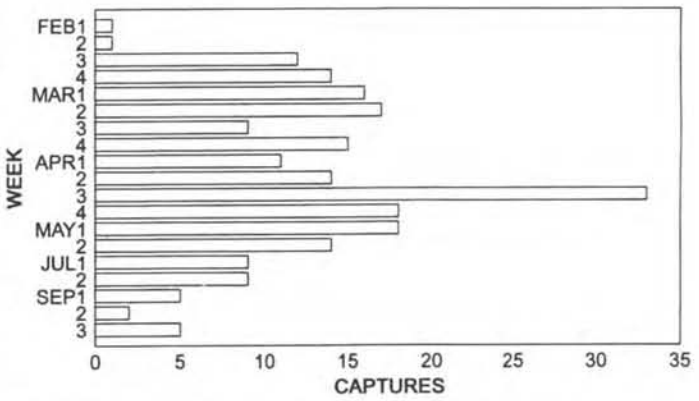

FIG. 2. Overall activity (number of captures by all pitfall drift fences) of the sand skink.

Cover boards and pitfall drift fences also were about equally capable of reflecting overall activity and total abundance of the sand skink accurately. Overall activity was low until late February, peaked in late April, and then diminished steadily over the summer and early autumn (Fig. 2; Telford 1959). Cumulative (over sites) number of cover boards with tracks and cumulative number of captures by four pitfall drift fences per site both were correlated strongly with overall activity ($r_S \geq 0.67$, $P < 0.05$, N = 19). Total abundance ranged from 5 to 26 individuals per site, yielding density estimates ranging from 125 to 650 individuals per ha (McCoy et al. 1999). Cumulative (over time) number of cover boards with tracks was correlated strongly with total abundance ($r_S = 0.82$, $P < 0.05$, N = 7). Cumulative number of individuals captured by four drift fences per site was correlated strongly with total abundance for about half of the replicates ($r_S = 0.43$–0.96, $P = < 0.05$–0.34, N = 7), probably reflecting the fact that the four selected pitfall drift fences were competing with twelve others for captures at each site.

Our results suggest that monitoring tracks under cover boards may be preferable to capturing individuals with pitfall drift fences for much of the survey work designed to recognize patterns of distribution and relative abundance of the threatened sand skink. Cover boards provide at least as reliable information as pitfall drift fences, plus they are less expensive and probably cause less environmental disturbance.

We illustrate how cover boards can be used effectively to sample the sand skink with a survey carried out in the vicinity of the seven

sites. The area encompassing the seven sites contained a heterogeneous grouping of habitats, ranging from swamps and swales to the xeric uplands in which the sand skink resides. The patchiness of this area provided an excellent opportunity to test existing ideas about habitat preferences of the sand skink (Christman 1992; McCoy et al. 1999; Telford 1959). We spaced cover boards at 5-m intervals along transects across the intersections of pairs of relatively dry habitats to document sand skink distribution and abundance more rigorously than typically has been done in the past at this scale. The habitat pairs available to us were scrub and scrubby flatwoods (N = 13 transects), scrub and pine flatwoods (N = 16 transects), and sandhill and scrubby flatwoods (N = 9 transects). Habitat descriptions are in Abrahamson and Hartnett (1990) and Myers (1990). Transect length was variable, depending on the perceived width of the transition zone between habitats. Regardless of length, each transect was divided into six sections: 0–10 m, 11–20 m, 21–30 m, 31–40 m, 41–50 m, and > 50 m from the terminus in what we pre-judged to be the better habitat for the sand skink (scrub > sandhill > scrubby flatwoods > pine flatwoods). Cover boards were set out in early June and then checked for tracks once in August and once in September, 1994. Along each transect, we noted the cover boards that had tracks under them, and then computed percentages of cover boards with tracks within each of the six sections. Percentages of cover boards with tracks along transects from scrub to scrubby flatwoods were 59% at 0–10 m, 55% at 11–20 m, 32% at 21–30 m, 7% at 41–40 m, and 0% thereafter; from scrub to pine flatwoods were 60% at 0–10 m, 50% at 11–20 m, and 0% thereafter; and from sandhill to scrubby flatwoods were 33% at 0–10 m, 0% at 11–20 m, 12% at 21–30 m, 25% at 31–40 m, and 0% thereafter. The sand skink left tracks more often under cover boards in scrub than in any of the other three habitats, and individuals penetrated farther from scrub into scrubby flatwoods than from scrub into pine flatwoods. These results confirm that the sand skink has a preference for drier habitats over wetter ones, and that our initial "educated guesses" about its relative preferences among habitats largely were accurate (McCoy et al. 1999).

Acknowledgments.—We thank Steve Christman, Paul Moler, and Sam Telford for reviewing earlier versions of the manuscript. The research was initiated in cooperation with Steven Godley and Bernard Kaiser (Biological Research Associates), and we thank them for their help. Access to study sites and funding were provided by Walt Disney Imagineering (WDI). We especially thank Jim Yawn of WDI for his help. Many students from the conservation group at USF provided assistance in the field.

Method for Attaching Radio Transmitters to Medium-sized Reptiles: Trials on Tuatara (*Sphenodon punctatus*)

GRAHAM T. USSHER

School of Environmental and Marine Sciences, University of Auckland
Private Bag 92019, Auckland, New Zealand
e-mail: g.ussher@auckland.ac.nz

The need to know why species translocations succeed or fail places added emphasis on post-release monitoring of individual animals. In New Zealand, a rare endemic reptile, the tuatara (*Sphenodon punctatus*), has recently been re-introduced to the first of many locations within its historical range. Tuatara are nocturnal, extremely cryptic, and often inhabit deep underground burrows which make them difficult to monitor. Hand catching of tuatara when they are active above ground has traditionally been the most efficient method of gaining morphological or dispersal information from individual animals, but can result in considerable environmental disturbance and disruption of tuatara natural activity patterns (see Cassey and Ussher 1999 for alternatives). Investigations planned to study the use of habitats by translocated tuatara required that a more efficient and less invasive method of yielding information be developed. Miniaturized radio transmitters were viewed as the most favorable method of obtaining this information.

The history of transmitter use with tuatara is brief. Hind-quarter mounted transmitters and temperature probes were used in the late 1960's–1970's, although attachment was for periods of nine days or less (Barwick 1982). In tracking trials during 1976–1977, New Zealand government scientists used a leather harness system for the then bulky transmitters (Newman 1980), but the design was not adopted because of fears for tuatara safety. Direct fixture of the transmitter to the dermis using surgical tape (C. Tyrrell, pers. comm.)

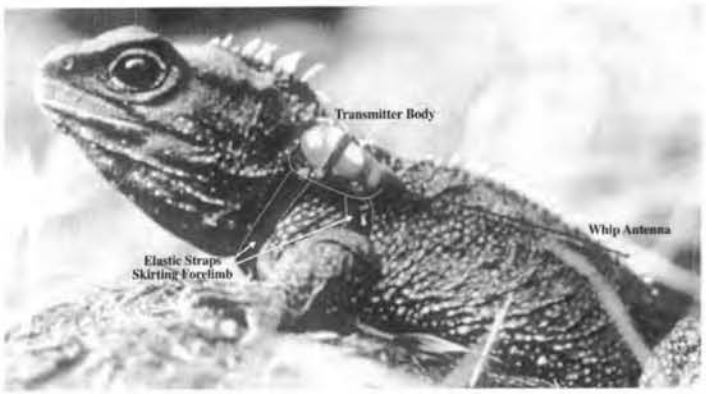

FIG. 1. Male tuatara (*Sphenodon punctatus*) fitted with a backpack harness and radio transmitter.

or with adhesive glues (B. Goetz, pers. comm.) has been attempted, although duration of trials on captive tuatara have been less than four weeks and adhesion beyond nine days in the field has yet to be successful.

The translocation study undertaken by me required that the attachment method be effective for periods of four months or more (long-term attachment) because I was unable to visit offshore island study sites on a regular or predictable basis. Potential avenues for long-term transmitter attachment were also constrained by aspects of tuatara biology. Tuatara grow to 700–1000 mm in total length and weigh from 300–800 g, meaning that force of contact with ground surfaces, and therefore wear on harness materials during locomotion, can be considerable. Compounding this is the tendency for tuatara to use small crevices as retreats, often among abrasive rock piles. Additional problems are an annual shedding cycle, susceptibility to dermal infection under non-porous skin coverings, and extremely slow rates of healing following surgical procedures (such as sub-dermal transmitter implantation) (R. Jacob-Hoff, pers. comm.).

During trials on captive animals, I focused on indirect transmitter attachment at the anterior region of the animal, using a modified harness system similar to that employed by Fisher and Muth (1995) for small horned lizards. The design was a modification of the harness constructed by N. Nelson (Victoria University, Wellington, New Zealand) and D. Newman (Department of Conservation, New Zealand). This design was successfully tested for 2.5 months (the average period between sampling visits to the islands) on captive animals and met additional criteria of being simple in design, readily repairable, and possible to assemble in the field from inexpensive materials. Below, I detail the final design of the transmitter harness, which can also be used on other similar-sized reptiles.

The radio transmitters used are tear-drop, single stage transmitters (Sirtrack Ltd.) measuring 20 mm x 10 mm with a 70 mm whip antenna and weigh < 4 g (Fig. 1). Ventral surfaces of transmitters are flat to maximize contact with transmitter pad and to aid in fit to tuatara body shape. The harness comprises two major sections: the transmitter pad, and the backpack straps (Fig. 1). The pad is constructed from a 30 mm x 20 mm strip of porous polypropylene webbing. Edges are heat sealed and smoothed to prevent abrasion of the dermis. Two lengths of polyester 13 mm wide braid elastic are sewn to each side of the longer edge of the pad. Two thin retainer straps of 4 mm wide polyester cord are sewn across the pad to act as anchors for the transmitter sitting atop the pad. Cyanoacrylic glue (Superglue™) is used to affix the transmitter to pad. When fitting the harness, the transmitter pad is placed on the upper ventral surface directly above either scapula with the transmitter aerial pointing posteriorly and the two straps pointing dorsally up and over the back. The most anterior strap is then pulled dorsally over the back, down anterior to the forelimb, under and across the ventral surface to rise posteriorly to the other forelimb and meet the diagonally opposite edge of the transmitter pad.

The procedure is repeated with the other strap, passing it over the back, down posterior to the forelimb and diagonally across the ventral surface. Both straps are pulled firmly to the pad edge and measured for trimming and attachment. Fit must be tight enough to account for the probable thorax expansion being exerted by the animal (adpression of the ribs when the animal relaxes following harness attachment will reduce tension in harness straps). Straps are trimmed to the required length and the ends are heat sealed to prevent fraying. Straps are attached to the pad with cotton thread using no more than 4–5 simple stitches. This serves as a 'weak link' which will part if the animal becomes entangled and will release it from the harness (and transmitter). Final weight of the transmitter package (transmitter + harness) is < 6 g.

For this study, 29 tuatara were fitted with backpack transmitters for a total of 8300 days. Harness performance was assessed by looking at wear of materials, reliability of weak links, and gross impact on animal welfare and behavior. Wear on materials over the 14–16 months was negligible in most cases. Harnesses endured temperatures from 3°C (winter) to 25°C (summer), frequent wetting and drying, abrasion against rock surfaces, and inundation with particulate soils and mud. Harness straps maintained elasticity throughout the study and webbing pads did not deteriorate. A single elastic strap frayed slightly at the edge. The weak links exceeded performance expectations. Trials on captive animals identified minimum stitching required to part under strain exerted by different sized tuatara (this may differ for smaller or larger species). Unfortunately, environmental degradation of weak links was not sufficiently taken into consideration. Harnesses worn by animals throughout the spring and summer months (minimum duration of 120 days) were discarded when autumn rains deteriorated the exposed cotton link fibers.

Impact on animal welfare was determined by presence of harness-induced injury to individuals or as loss of body condition compared to tuatara without transmitter packages released at the same location. Animals in one release population (N = 9) showed no signs of physical injury, but 80% (N = 20) of tuatara on the other island exhibited varying degrees of abrasion under one or both axillae. This effect was attributed to the larger-sized tuatara in the unaffected population (mean snout-vent length [SVL] males: 265 mm (± S.E. 10 mm); females 247 mm (± S.E. 23 mm), while those in the affected population were inherently smaller individuals (SVL males: 203 mm (± S.E. 4 mm); females 174 mm (± S.E. 1 mm). This influence of body size on harness effect did not eventuate during trials, probably because tuatara in trials were large animals of similar size to those in the unaffected population.

In most cases (13 out of 16), abrasion only resulted in damage or removal of scales within a small area of the axilla. In three cases, abrasion was sufficient to also break the skin surface, but abrasions healed within two months. It is probable that, shortly after fitting, the elastic straps of the harness stretch a small amount and conform to the animal's body shape, with most abrasive stress being applied during this easement period. Replacement harnesses were fitted less firmly to animals and no further problems of strap-induced abrasion were recorded. Additional abrasion problems in the form of small cuts to the dorsal spine projections were seen on three animals, and seem to have also been caused by overly tight harnesses.

The impact of harnesses on foraging and mating behavior was of paramount concern at the study's conception. Increased probability of predation was not an important consideration, as it is unlikely that the natural predators of tuatara are able to prey on adult individuals in forested habitats (but see Saint Girons et al. 1980 for predation by Australasian harriers (*Circus approximans*) in modified grassland habitat). All individuals fitted with transmitter packages were mature adults. Analysis of fecal pellets from transmittered and non-transmittered animals indicated no recognizable difference in either the type or size of prey appearing in diets. Effect of transmitter packages on foraging efficiency would manifest itself as long-term weight loss in affected animals. Weight changes for tuatara fitted with transmitters were comparable to weight changes for animals without transmitters (e.g., release population 1: % body weight change since release for tuatara with harnesses = -3.6%–0.9% [N = 2]; without harnesses = -1%–10.8% [N = 5] over the same period). Additionally, mating behavior was exhibited by both transmitted and non-transmittered animals during the study. Differential mating success of transmittered and un-transmittered animals was not investigated.

In summary, the backpack harness system for attaching radio transmitters to medium-sized reptiles such as tuatara is a safe, reliable design which ensures the safety of the study animal and enables long-term (> 4–5 months) attachment. Correct fitting of harnesses will prevent abrasion seen for some tuatara in this study. Materials used for the harnesses weathered New Zealand seasonal climatic variations as well as the wear caused by tuatara habits. Weak links incorporated to protect study animals need to be improved to ensure that harnesses are not shed solely due to climate-induced degradation of cotton links. Perhaps sealing cotton links in weatherproof materials will ensure greater efficiency. Harness materials may also have to be modified for use on smaller reptiles to prevent abrasion-related problems seen in this study.

Acknowledgments.—Auckland Zoological Park staff (especially Richard Jacob-Hoff and Martin Bell) helped with captive trials. Sirtrack Tracking and Telemetry Systems Ltd (Havelock North, New Zealand) supplied materials for captive trials and transmitters used in the main study. The tuatara translocation project was funded by the World-Wide Fund for Nature (WWF(NZ)) and the NZ Lotteries Board grant number SR9116. Many thanks also to Don Newman, John Craig, Claudine Tyrrell, Nicky Nelson, Bernard Goetz, and two anonymous referees for commenting on drafts of the manuscript.

A Vietnamese Trapping Technique for Capturing Butterfly Lizards (*Leiolepis*)

THOMAS ZIEGLER
Zoologisches Forschungsinstitut und Museum Alexander Koenig
Adenauerallee 160, D-53113 Bonn, Germany
e-mail: uzsmdb@uni-bonn.de

During recent field studies in Vietnam (June–September 1997, August–October 1998), a simple but very effective trapping technique to live capture butterfly lizards (*Leiolepis* sp.) was observed at Cua Lo (Nghe An province). The trap was used to capture adult specimens of *Leiolepis r. reevesii* at the entrances to their burrows and consists only of bamboo cane and nylon line.

A section of bamboo cane approximately 40 mm long and with 27 mm internal diameter (wall thickness about 5 mm) is required. The cane is punctured at the top about 10 mm away from the front end (Fig. 1a: A). A second bamboo stick (approximately 210 mm long, 10 mm wide and 1 mm thick) consisting of young and therefore very elastic bamboo is needed (Fig. 1a: B). It is important that this flexible stick is neither too weak nor too strong, to both assure successful trapping and avoid injuries to the trapped lizard. The stick is fixed along the longitudinal axis of the bamboo cane on the underside. It projects approximately 140 mm from the rear edge of the bamboo cane. For attachment, a nylon line is drawn repeatedly through the bamboo cane and firmly connected to the bamboo stick immediately in front of and behind the bamboo cane (not obvious from Fig. 1). This simple but adequate attachment of the flexible stick to the rigid bamboo cane facilitates movement of the stick to adjust leverage during use. This projecting part of the stick is notched 10 mm from the end to allow attachment of a nylon line (about 220 mm in total length). Forty mm from the knot at the stick, the end of a solid, non-elastic bamboo wedge (approximately 50 mm long, 5 mm wide and 7 mm thick) is tied to the nylon line (Fig. 1a: C). On the upper half of this wedge, a notch (about 4 to 5 mm deep) is required which can hold the upper rear edge of the bamboo cane. The remaining nylon line (about 150 mm from the upper end of the wedge) is threaded from outside to inside through the puncture on the top of the front end of the bamboo cane (Fig. 1a: D). Finally, a small loop is made at the end of the nylon line (a small metal ring can also be used) to allow construction of a noose for capturing the butterfly lizards.

To set the trap, the notch in the wedge is carefully fitted on to the back end of the bamboo cane, so that the linked stick gets tightened (Fig. 1b). Then a noose of about the size of the internal diameter of the bamboo cane is made in the end of the nylon line, which finally is carefully fit by hand to the inner wall of the anterior opening of the bamboo cane. The trap is now carefully introduced with its anterior opening directed into the entrance of an inhabited *Leiolepis* burrow (Fig. 2). Upon exiting its burrow, the butterfly lizard has to pass through the bamboo cane and place its head or body into the noose. As the lizard approaches the opening of the bamboo cane, it will push the basal part of the wedge and release tension in the tightened stick which will spring back and tighten the nylon line. As a consequence, the noose is tightened on the neck or anterior body of the lizard and holds it on to the tube of the trap. Now the trap can be taken out of the entrance of the burrow and the noose carefully removed from the lizard. To prevent overheating of the trapped lizard and to avoid possible injuries from the nylon noose, the lizard should be set free from the trap as soon as possible. However, because most lizards were captured by the noose between the front and hind limbs, injuries were rare.

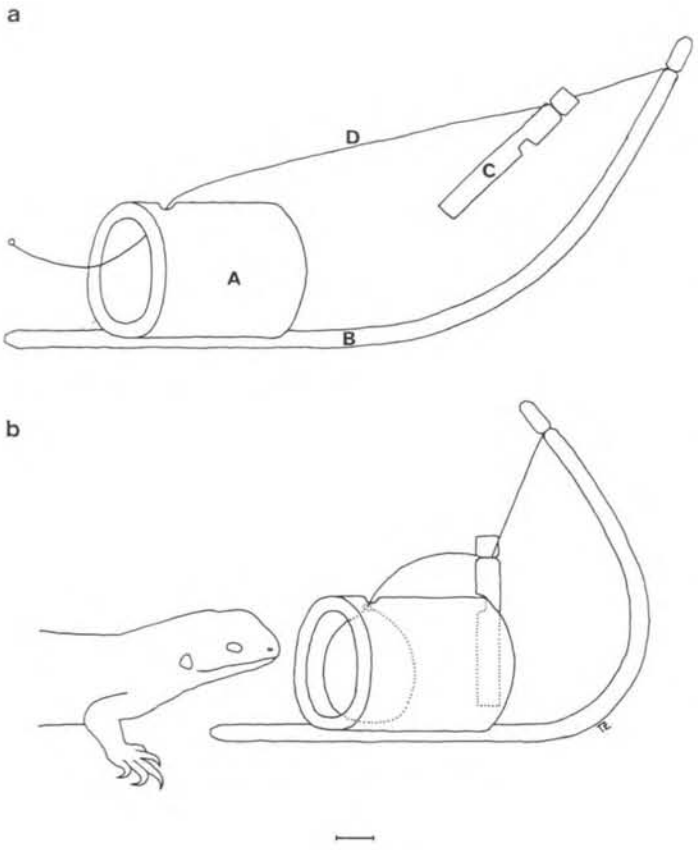

FIG. 1. Schematic drawing of the described bamboo trap (a, in resting position and b, armed). A: rigid bamboo cane, B: flexible bamboo stick, C: rigid bamboo wedge, D: nylon line. Scale bar equals 10 mm.

Local children reported capturing up to 20 to 30 lizards per day, depending on the number of traps used and the number of inhabited burrows found. However, lizards are less likely to exit their burrow entrances with a trap present and sometimes try to dig another way out. Writing about *Leiolepis belliana*, Smith (1935) probably referred to the same trapping technique used by Thai hunters in his statement "The Siamese trap them by means of a cleverly constructed spring noose placed at the entrance to the burrow." An advantage of this effective trapping technique is that lizard burrows do not have to be destroyed. Because it mainly consists of natural products, the trap is inexpensive (about $0.50 per trap in 1998), and it is easily constructed and used. It also should be possible to construct such a trap from other materials such as timber or plastic, and to apply the trapping technique to other burrow-inhabiting species. For example, it could be used to capture spiny-tailed lizards (*Uromastyx*), the sister group of the genus *Leiolepis* (Moody 1980; Peters 1971). Vyas (1990) already presented a similar trapping technique to capture *Uromastyx hardwickii* by using a plastic noose set at the entrance of the lizard's burrow and tied to a long stick. Leaving its burrow, the lizard passes the noose, which snares the lizard anterior to the hind limbs. When the lizard reenters its burrow, the long stick acts as an anchor at the relatively smaller entrance. According to Vyas (1990) a trapper may catch 50 to 80 lizards in a day using this simple method. Bouskila (1985) described another interesting method for capturing *Uromastyx aegyptia* and other burrow-inhabiting lizards using a "hooped fishing net trap" instead of a noose (for trapping of burrow-inhabiting tortoises, see Recht 1981).

FIG. 2. The trap at the entrance to a burrow of *Leiolepis r. reevesii* at Cua Lo beach, Vietnam.

Although I present a Vietnamese trapping technique for scientific purposes, it should be mentioned that laws exist in Vietnam since 1989 concerning the protection of endangered fauna, and since 1992 restricting or prohibiting the trade of endangered species. According to the Red Data Book of Vietnam (Ministry of Science, Technology and Environment 1992) *Leiolepis belliana guttata*, currently *Leiolepis guttata* (Peters 1971, Darevsky and Kupriyanova 1993) is listed in the category "threatened."

Acknowledgments.—I thank Daniel D. Beck, Wolfgang Böhme, Jörn Köhler, Miguel Vences, Stefan Weitkus and an anonymous reviewer for critical comments on the manuscript. Thanks also to Wolfgang Böhme, Manfred Niekisch, Vo Quy, Hoang Xuan Quang, and Cao Tien Trung for their support in conducting the German-Vietnamese cooperation project. Field studies in Vietnam were financially supported by the Volkswagen Foundation (project no. I/72 843), and by a grant of the "Graduiertenförderung" (GrFG NW, no. 1 26 10) in combination with a grant of the German Academic Exchange Service (DAAD, no. 213/327/501/7).

Estimating Egg Mass in Lizards Using X-radiography

MICHAEL J. ANGILLETTA JR.
Department of Biology, University of Pennsylvania
Philadelphia, Pennsylvania 19104-6018, USA
e-mail: angillet@sas.upenn.edu

Data on age-specific reproduction are critical to testing life history theory, and frequently yield greater insight regarding the evolution of life histories (Stearns 1992). Such data can be difficult to acquire for reptiles in natural populations, because determination of egg masses and clutch mass may require destructive sampling or that individuals be maintained in captivity until oviposition. X-radiography is a non-invasive means of determining egg number and egg size in reptiles (Gibbons and Greene 1979; Hinton et al. 1997; but see Kuchling 1998), and has been widely used on individuals to determine population demographics (e.g., Congdon and van Loben Sels 1991, 1993). Another potential application of X-radiography is estimation of egg mass (Congdon et al. 1983; Girardin 1993). Here, I demonstrate that: 1) X-radiography produces adequate resolution of eggs in small lizards, and 2) egg dimensions can be used to accurately predict egg mass in the lizard *Sceloporus undulatus*. These data suggest that X-radiography is a valuable tool for measuring age-specific reproductive traits in lizards.

In the springs of 1997 and 1998, I collected gravid females of *S. undulatus* on the Savannah River Site, Aiken, South Carolina, USA. X-radiographs of these females were made with a table-top unit (Emerald 130, Eureka Xray Tube Co., Chicago, Illinois, USA). Lizards were photographed while lying on their dorsal surface, at a distance of 100 cm from the X-ray tube, using Cronex 10 film and a fast detail screen (STERLING Diagnostic Imaging, Newark, Delaware, USA). X-radiographs were taken over a wide range of output settings to determine settings that maximized clarity of eggs.

To determine the relationship between egg size and egg mass, I used eggs laid by gravid *S. undulatus* in the laboratory. Gravid females were collected from a population in Burlington County, New Jersey, USA, during the summers of 1997 and 1998. Females were transported to the laboratory, where they were maintained in 6 L terraria on a layer of damp sand or sphagnum moss. Terraria were checked twice daily for newly laid eggs. When eggs were discovered they were removed and weighed to the nearest 0.01 mg using an electronic balance. Egg width and egg length were measured to the nearest 0.01 mm with digital calipers. I used multiple linear regression to produce a model to predict egg mass based on egg length and egg width.

A sensitivity analysis of the model was performed to determine the accuracy with which egg length and egg width must be measured to satisfy the requirement of estimating egg mass within 5% of actual mass. Average length and average width were used as values for the regression model parameters to calculate a reference value for predicted egg mass. Length or width was then varied systematically in 1% intervals and predicted egg mass was recalculated. Percent deviation of the new prediction from the reference value was used as an indication of percent error in estimation of egg mass associated with a given percent error in measurement of egg length or egg width.

A total of 175 eggs from 22 females were measured. Both egg length and egg width were significantly correlated with egg mass (Fig. 1). Multiple linear regression produced the following model, relating egg length (L), egg width (W), and egg mass (M),

$$M = 0.0378 \cdot L + 0.081 \cdot W - 0.682$$

The model explained 92% of the variation in egg mass ($F_{2,172} = 965.51$, $p < 0.01$, adj. $r^2 = 0.92$). The average residual was $3 \cdot 10^{-10} \pm 0.002$ indicating that the data were distributed evenly around the regression line. When the regression equation was used to predict egg mass for the 175 eggs, average error in predicted egg mass was $0.1 \pm 0.6\%$. The absolute deviation of predicted egg mass from actual egg mass averaged $3.1 \pm 0.4\%$. Thus, the regression equation was capable of predicting egg mass with high accuracy.

Using X-radiography procedures described above, I obtained clear images of lizard eggs. An output of 5 mAs and 44 kV provided the sharpest detail for measurement of egg dimensions (Fig. 2). Similar output can be achieved using a less expensive, portable X-ray unit (Model 903, MinXray Inc., Northbrook, Illinois, USA). Therefore, X-radiographs can be taken at a remote field station or, if necessary, in the field. Such a design would permit determination of egg mass and clutch mass with little disturbance, and would be ideal for use with animals included in demographic studies.

Measurements of egg dimensions from X-radiographs should produce highly accurate estimates of egg mass. Sensitivity analysis

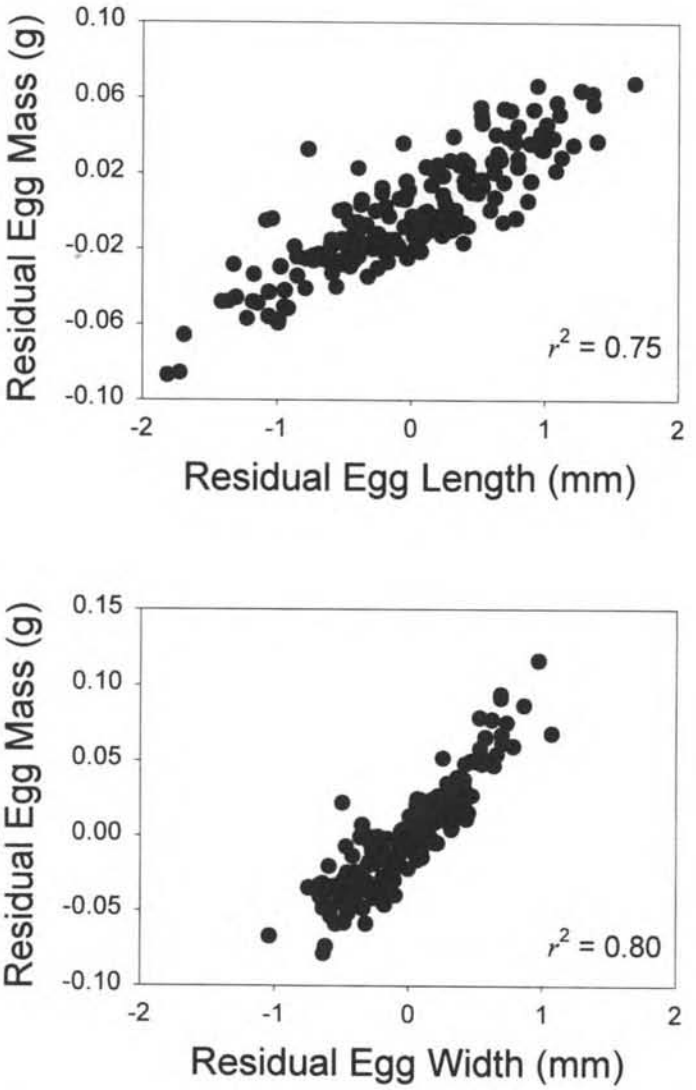

FIG. 1. Relationships between residual egg dimensions and residual egg mass in the lizard *Sceloporus undulatus*. Partial correlations for both egg length (N = 172, $t = 22.6$, $p < 0.001$) and egg width (N = 172, $t = 26.2$, $p < 0.001$) were highly significant.

FIG. 2. X-radiograph of a gravid female obtained with an output of 5 mAs and 44 kV (see text for details). This individual was carrying eight eggs, all of which were clearly visible and could be measured directly from the X-radiograph.

indicates that a deviation of less than 5% from actual egg mass requires that egg length and egg width each be measured within 0.17 mm of actual values. This is a very reasonable margin of error, considering the accuracy of digital calipers (± 0.01 mm). The most likely source of error in egg dimensions is magnification of the image, caused by the X-ray technique (≈6.4%, Congdon and van Loben Sels 1991). The magnitude of error caused by image distortion can be reduced by including objects of standard length in each X-radiograph, which can be used to determine a correction factor for egg dimensions (Graham and Petokas 1989). To assess the accuracy of egg dimensions determined from X-radiographs, I measured egg dimensions of a clutch of eggs laid one day after being X-rayed. On average, egg length and egg width measured from X-radiographs deviated 0.15 mm and 0.13 mm, respectively, from measures of actual eggs (N = 5), which would result in an average error in egg mass estimation of 4%. At least one source of error would be eliminated when egg dimensions are obtained from X-radiographs. Because lizard eggs have a flexible shell, measures of egg dimensions are prone to error resulting from compression of the egg. X-radiographs provide a fixed image for measurement, eliminating errors resulting from compression by hands or calipers.

I conclude that egg mass, and thus reproductive output and relative clutch mass, in *S. undulatus* can be inferred from dimensional measurements of eggs in X-radiographs. This technique provides a valuable tool for following reproductive output of individuals in a demographic setting, and will add to our existing knowledge of reproductive patterns in reptiles. Undoubtedly, predictive equations for estimating egg mass from X-radiographs can be generated for other species (e.g., Girardin et al. 1993). Future studies of reproductive allocation should exploit the advantages of X-radiography to determine aspects of offspring size, as well as offspring number.

Acknowledgments.—I thank R. S. Winters and M. W. Sears for laboratory and field assistance. D. Kling helped with initial attempts to X-radiograph lizards. J. Congdon provided valuable advice and logistical support. M. Dorcas, C. Spencer, and R. Seigel helped improve the manuscript. Animals were collected with permission from the NJDEP Division of Fish, Game, and Wildlife. All work was performed in accordance with the regulations and recommendations of the Institutional Animal Care and Use Committees of the University of Georgia and the University of Pennsylvania.

How many times have you been collecting on a rainy night and seen a salamander wriggling across the road? You stop the car and jump out to get the slippery creature, only to see the high-beams of a car quickly coming up behind you. You are left with three choices: 1) step off to the side of the road and watch the animal get crushed; 2) try to quickly grab the small, slippery animal (a difficult task on flat, wet roads); or 3) get back in your car and drive off, never knowing the identity of the animal or if the animal survived. Even if you do manage to capture the animal, when you rush back to your dark car and drive off, the wet squirming animal may escape into the vehicle before you can secure it into a container. Shaffer and Juterbock (1994) also suggest that night driving to collect herpetofauna can be dangerous and that safety issues should be considered. After many frustrating encounters while night driving, we developed a simple, inexpensive device for quickly and safely retrieving amphibians, reptiles, and other small animals. Our device functions similarly to the skink scooper (Brattstrom 1996), but

has the additional advantage of being transparent and having a very pliable lip. This flexibility allows the scoop to be pressed flush against uneven surfaces.

The device is made from a one-, two-, or three-liter clear polyethylene soft drink bottle. Soft drink bottles equipped with thicker opaque, plastic bases work best for lids, as they provide a snug fit when pushed into the bottle opening. Most soft drink companies have stopped putting the thicker opaque bases on their bottles, but the naked bases still provide a relatively snug fit.

The scoop is constructed by cutting the bottom off of the bottle just above the opaque base, or if the bottle lacks a base, the cut can be made 1–2 cm above the point where the base tapers inward (Figs. 1A and B). The base is inverted and pushed into the opening of the bottle to form a snug-fitting lid.

A V-shaped notch about 3–5 cm wide and about 2 cm deep should be cut into the bottom lip of the bottle (Fig. 1C). Placing the notched side of the bottle on the roadway greatly facilitates the capture of small animals that tend to dart off in random directions, because it allows the collector to position the animal head-first and part way inside the bottle prior to capture. The animal is then prodded with the bottle base or a finger to run into the scoop. The notch improves capture rate substantially and also provides a convenient place to grasp the base/lid when removing it from the scoop. The scoop's versatility can be increased by making two different-sized notches on opposite edges of the bottle opening.

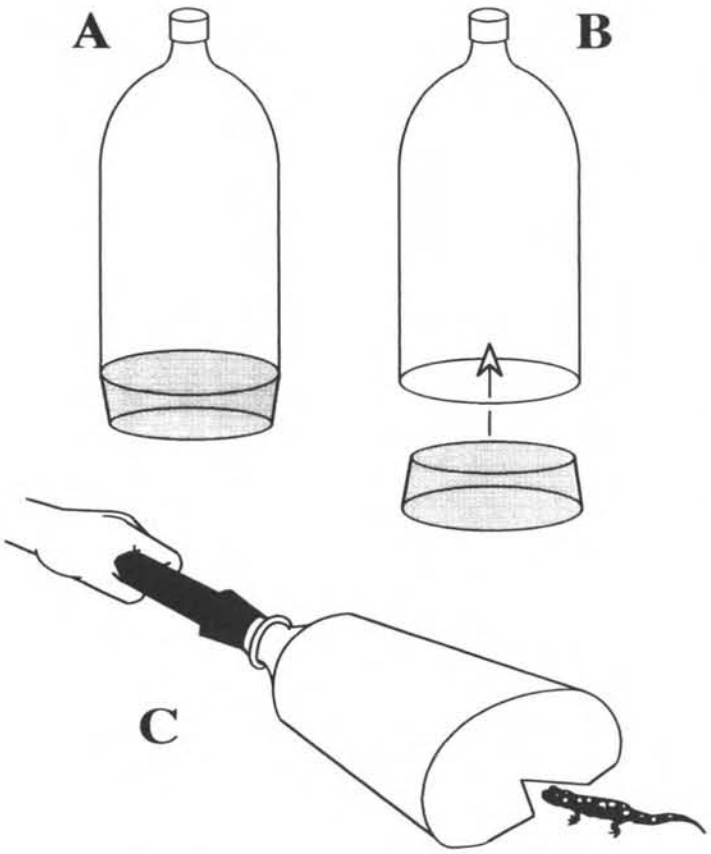

FIG. 1. The scoop is made from (A) a polyethylene soft drink bottle with (B) the base cut off and inverted to act as a lid. (C) A V-shaped notch and a flashlight should be added to make the scoop more useful.

On the other end, the screw cap can either be left on the bottle, removed to form an air hole or access port, or replaced with a small flashlight to make it more useful at night (Fig. 1C). The Tuff Lite® by Garrity® fits best in 3-L bottles, uses two 'AA' batteries, and has the on/off switch in the end of the flashlight. Depending on the soft drink brand, the opening may have to be enlarged slightly using fine sandpaper. The rubber covering on the end of the Tuff Lite® should be peeled back so that the end of the flashlight can be inserted into the opening, then the rubber sheath is rolled back onto the threads of the bottle mouth. By doing this, the rubber covering grips the threads and holds the flashlight securely on the scoop. To avoid losing the screw cap when using the flashlight, the cap can be attached to the inside of the original base with velcro, or connected to the neck of the bottle with a short, knotted string punched through the center of the cap. At night, the light aids in positioning the notch, helps to disorient the animal momentarily prior to capture, and effectively illuminates the animal after capture so it can be identified. The modified herp scoop can be completely assembled for under US $5.00 which includes the cost of the flashlight.

We have found the modified herp scoop very useful for rapidly catching many species of herpetofauna on wet roadways. We have even used this device to capture large ranids (*Rana*), small venomous snakes (*Agkistrodon* and *Sistrurus*), musk-emitting snakes (*Thamnophis* and *Nerodia*), tarantulas, and small mice on the road at night. When captive sirens (*Siren*) or amphiumas (*Amphiuma*) jump out of their tanks onto the floor, the herp scoop is helpful in retrieving them and could also be used in capturing them from seines or dredges.

A major advantage of the scoop is that the pliable plastic can be molded to fit irregular surfaces. While it conforms nicely to road surfaces, the scoop is also effective for catching salamanders in rock crevices, cliff faces, or rocky stream beds. Since salamanders often sit with their heads extending from their retreat, it is best to hold the scoop vertically with the opening molded to fit the lip of the retreat. The salamander can often be coaxed out of the retreat and into the scoop by gently touching its tail or back with a slender stick. Although this technique works extremely well, the real advantages of this inexpensive device are more often realized during road cruises conducted during rainy nights on busy roadways, where concern for personal safety often conflicts with successful animal collection.

Acknowledgments.—We thank Lynnette Sievert, Debby Andreadis, Kym Campbell, and David Edds for comments on the manuscript.

A Novel Snake Restraint Device

RICHARD E. MAULDIN

The restraint and immobilization of snakes without the use of chemicals have a variety of research and veterinary applications. These applications include scale counts, band counts, and delicate invasive procedures like blood or tissue sampling and introduction of an oral catheter. Techniques requiring secured snakes are usually accomplished by two handlers, one holding the snake and the other performing the procedure. A wide variety of snake restraint devices and techniques have been described. Some involve allowing snakes to crawl into transparent plastic tubes which are either flexible (Johansen 1959; Sutherland and Hampton 1961), or rigid (Presst 1971), or made of a series of rigid tubes with decreasing diameters (Murphy 1971). Noose or strap sticks frequently have been used (Bellairs 1967; Conant 1958; Fowler 1978; Gregory et al. 1989; Schmidt and Davis 1941) and have been combined with clear plastic tubing to form a "noose tube" (King and Duvall 1984). Many devices have involved using tape or Velcro strips to restrain snakes against flat boards (Ward and Harrell 1978) or wooden dowels (McDonald 1964), or in wooden troughs (Luck and Keebler 1929). Lidded buckets with notched lips have allowed the snake's posterior half to be handled while the head was restrained in the bucket (Gillingham et al. 1983), while plastic freezer containers with holes in the lid have also been used to hold a snake's head during handling (Freed and Freed 1983).

These methods have been useful in various circumstances, but they also have limitations. Some limit the handler's access to all parts of the snake, while others leave enough of the snake unrestrained that injury to the animal can occur as it struggles to escape. Many of these techniques require construction of the restraining device. Here we describe a device which can be purchased and used "off the shelf," and a method whereby a single individual can immobilize a snake in a straight position indefinitely.

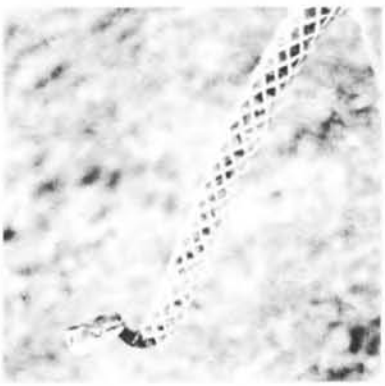

FIG. 1. An effectively immobilized California kingsnake (*Lampropeltus getula californiae*).

Wire mesh cable holders operate on the same principles as a finger puzzle, a tube of woven fiber which, when longitudinally compressed, allows the insertion of cylindrical objects. Subsequent longitudinal extension of the tube tightens the fibers around the object, preventing its withdrawal. Cable holders are available through electrical equipment suppliers and come in a variety of lengths and diameters. Compression of the ends of the cable holder toward the center maximizes the internal diameter for insertion of the snake. The handles of the cable holder are double-looped and easily spread at the time of insertion, although we find that modification of the handles by cutting the loops and putting caps on the wire ends increases the ease of operation. After the snake is advanced through the cable holder to the desired position, the cable holder is drawn to full length by pulling on the handles. This secures the snake in a rigid, straight position and permits it to be controlled by one person using one hand. The wide gaps of the mesh of the cable holders permit easy visual observations, such as scales counts, and invasive procedures, such as blood draws. Optimum immobilization and stability are achieved if the size of the internal diameter of the cable holder is selected correctly for the size of the snake (Figs. 1–2). The diameter of the snake should be slightly greater than the diameter of the tightened cable holder. We have successfully applied this device to a variety of species besides those in the figures, including bullsnake (*Pituophis melanoleucas*), corn snake (*Elaphe guttata*), Dumeril's boa (*Acrantophis dumerili*), and Haitian boa (*Epicrates striatus striatus*). We have not attempted to insert any dangerously venomous snakes into a cable holder, although once properly secured in a cable holder of appropriate size, manipulations should be easily conducted in a safe manner.

FIG. 2. The effects of using a cable holder with too large diameter, allowing a brown tree snake (*Boiga irregularis*) too far beyond the end of the cable holder.
